With cryptocurrency prices remaining extremely volatile even as interest in cryptos from credible investors has been rising, and legacy financial institutions—including ourselves—have been launching new crypto products and services, crypto is undoubtedly Top of Mind. Amid the recent volatility, we ask experts whether cryptos can and should be considered an institutional asset class, including Galaxy’s Michael Novogratz (Yes; the mere fact that a critical mass of credible investors is engaging with cryptos has cemented this), NYU’s Nouriel Roubini (No; cryptos have no income, utility or relationship with economic fundamentals), Grayscale’s Michael Sonnenshein (Yes; their strong rebound in 2020 reassured investors about their resiliency as an asset class), and GS’s own Mathew McDermott (clients increasingly say “yes”). And GS research analysts also weigh in. We then speak to former SEC advisor Alan Cohen, Trail of Bits’ Dan Guido, and Chainalysis’ Michael Gronager to explore the regulatory, technological, and security obstacles to further institutional adoption.

“...We’ve now hit a critical mass of institutional engagement [in crypto]. Everyone from the major banks to PayPal and Square is getting more involved, which is a loud and clear signal that crypto is now an official asset class.

- Michael Novogratz

Bitcoin and other cryptocurrencies aren’t assets. Assets have some cash flow or utility that can be used to determine their fundamental value... Bitcoin and other cryptocurrencies have no income or utility.

- Nouriel Roubini

I have yet to find somebody who has really done their homework on crypto assets that isn’t truly amazed by the potential for the asset class.

- Michael Sonnenshein
We provide a brief snapshot on the most important economies for the global markets

**US**

**Latest GS proprietary datapoints/major changes in views**
- We now expect core PCE inflation to peak at 2.8% in May and fall to 2.25% by year-end 2021 after the strong April CPI print.

**Datapoints/trends we’re focused on**
- Taper timeline; we think the Fed will only start to hint at tapering in 2H21 and begin to taper in early 2022.
- Fed liftoff; if our taper timeline is right, then liftoff will probably not be on the table for about two years.
- Unemployment; we expect a somewhat less front-loaded jobs recovery, but still see unemployment at 4% by year-end 2021.

**Pandemic distortions to core inflation should peak soon**
Core PCE and contributions to its 2020-22 deviation from trend

![Core PCE Inflation (YoY) and GS Forecast](image)

**Source:** Department of Commerce, Haver Analytics, Goldman Sachs GIR.

**Europe**

**Latest GS proprietary datapoints/major changes in views**
- We raised our 2021 UK GDP forecast to 8.1% based on upward revisions to GDP and stronger growth momentum.

**Datapoints/trends we’re focused on**
- Euro area lockdowns, which should continue to loosen ahead of a summer reopening, supporting a growth surge.
- Tourism season; delaying int’l travel into early August would reduce av. growth in Southern Europe by 0.25 pp in Q2/Q3.
- Vaccine pace, which has more than doubled since March, putting Europe on track to vaccinate 50% of the pop. by mid-June.

**Emerging Markets (EM)**

**Latest GS proprietary datapoints/major changes in views**
- We lowered our Q2 and full-year 2021 India real GDP growth forecasts to -20.5% qoq ann. and 9.7% yoy, respectively.

**Datapoints/trends we’re focused on**
- Virus growth, which remains high in India and parts of LatAm.
- China turning point; with the V-shaped recovery complete, the policy focus is shifting to long-term stability and growth.
- Impact of rising US yields, particularly rising real rates, which remains a key risk for EMs.
- Rising oil prices; we see Brent crude prices rising to $75/bbl over 3m, which should support EM HY oil exporters.

**A COVID-19 tidal wave for parts of EM**
Daily change in confirmed cases (7dma), thousands

![A COVID-19 tidal wave for parts of EM](image)

**Source:** JHU, Goldman Sachs GIR.

**Japan**

**Latest GS proprietary datapoints/major changes in views**
- We lowered our 2021 and CY21 real GDP growth forecasts to 1.8% qoq ann. and 2.6%, respectively, after the imposition of a third state of emergency, and see a more back-loaded recovery.

**Datapoints/trends we’re focused on**
- Pent-up demand, which should boost spending by ¥3.1tn (1% of consumption) and ¥3.9tn (1.3%) in the first and second years after reopening, respectively.
- Fiscal policy; additional support is a possibility.
- BoJ policy; we expect the status quo in policy to remain for a long time with little impact from the inflation outlook.

**Emerging Markets (EM)**

**Latest GS proprietary datapoints/major changes in views**
- We lowered our Q2 and full-year 2021 India real GDP growth forecasts to -20.5% qoq ann. and 9.7% yoy, respectively.

**Datapoints/trends we’re focused on**
- Virus growth, which remains high in India and parts of LatAm.
- China turning point; with the V-shaped recovery complete, the policy focus is shifting to long-term stability and growth.
- Impact of rising US yields, particularly rising real rates, which remains a key risk for EMs.
- Rising oil prices; we see Brent crude prices rising to $75/bbl over 3m, which should support EM HY oil exporters.

**Goldman Sachs Global Investment Research**
With cryptocurrency prices remaining extremely volatile on news about regulatory crackdowns, environmental concerns and heightened tax scrutiny even as interest in crypto assets from credible investors has been rising and legacy financial institutions—including ourselves—have been launching new crypto offerings, crypto is undoubtedly Top of Mind. We first wrote about bitcoin in 2014 and cryptos more broadly in 2018, exploring the potential and risks of the crypto ecosystem. Amid the recent volatility, here we focus on whether crypto assets can be considered an institutional asset class.

We start by speaking with Michael Novogratz, Co-founder and CEO of Galaxy Digital Holdings, which is active in crypto investing and trading, asset management, and venture financing. He argues that the mere fact that a critical mass of credible investors and institutions is now engaging with crypto assets has cemented their position as an official asset class. And, despite the price volatility, he doesn’t see the institutional interest in bitcoin, which he primarily views as a convenient store of value, waning as long as the current macro and political backdrop—in which the government has no imperative to stop spending on social issues that the Fed is largely financing—continues, and crypto remains in the adoption cycle.

Michael Sonnenshein, CEO of Grayscale Investments, the world’s largest digital asset manager, agrees that institutional investors now generally appreciate that digital assets are here to stay, with investors increasingly attracted to the finite quality of assets like bitcoin—which is verifiably scarce—as a way to hedge against inflation and currency debasement, and to diversify their portfolios in the pursuit of higher risk-adjusted returns. Even though crypto assets have behaved as anything but a diversifier over the past year—selling off more than traditional assets as the COVID-19 pandemic set in—he says that their faster and stronger rebound in 2020 only reassured investors about their resiliency as an asset class.

But what makes a crypto like bitcoin—which has no income, no practical uses and high volatility—a good store of value? Novogratz’s answer: because “the world has voted that they believe” it is. Zach Pandi, GS Co-Head of Global FX, Rates, and EM Strategy, largely agrees, arguing that bitcoin’s potential for widespread social adoption given its strong brand on top of its other properties, such as its security, privacy, transferability and the fact that it’s digital makes it a plausible store of value for future generations. And he believes that institutional investors today should treat bitcoin as a macro asset, akin to gold.

GS commodity analyst Mikhail Sprogis and Jeff Currie, Global Head of Commodities Research, for their part, argue that cryptos can act as stores of value, but only if they have other real world uses that create value and temper price volatility. This, they say, best positions cryptos whose blockchains offer the greatest potential for such uses, like ether, to become the dominant digital store of value. More broadly, Currie contends that cryptos are a new class of asset that derive their value from the information being verified and the size and growth of their networks, but that legal challenges to their future growth loom large due to their decentralized and anonymous nature.

And Nouriel Roubini, professor of economics at NYU’s Stern School of Business, entirely disagrees with the idea that something with no income, utility or relationship with economic fundamentals can be considered a store of value, or an asset at all. Despite the recent crypto mania, he doubts the willingness of most institutions to expose themselves to cryptos’ volatility and risks, which the volatile price action in recent days has served as a stark reminder of.

Christian Mueller-Glissmann, GS Senior Multi-Asset Strategist, then makes the case that for an asset to add value to a portfolio, it has to offer either an attractive risk/reward or low correlations with other macro assets, and preferably both. He finds that a small allocation to bitcoin in a standard US 60/40 portfolio since 2014 would’ve led to strong outperformance, owing both to higher risk-adjusted returns for bitcoin compared to the S&P 500 and US 10y bonds, as well as diversification benefits from relatively low correlations between bitcoin and other assets. But with this outperformance largely owing to only a handful of idiosyncratic bitcoin rallies, he concludes that bitcoin’s short and volatile history makes it too soon to conclude how much value it adds to a balanced portfolio.

But beyond the debatable role of cryptos as a store of value and investible asset, does the broader crypto ecosystem provide promise for investors? Novogratz and Sonnenshein strongly believe that the answer is yes, given a myriad of potential use cases for crypto assets. In particular, Novogratz sees the three biggest developments in the crypto ecosystem—payments, Decentralized Finance (DeFi), and non-fungible tokens (NFTs)—mostly being built on the Ethereum network, which suggests substantial upside for it and various DeFi applications. But Roubini contends that few successful applications of blockchain technology exist today. And he sees many potential corporate uses of it as “BINO”—Blockchain In Name Only. In short, he’s skeptical that blockchain technology will prove revolutionary because “the idea that technology can resolve the question of trust is delusional.”

Mathew McDermott, GS Global Head of Digital Assets, then explains why GS has (re)engaged in the space—in two words: client demand—and how interest in cryptos differs between client types—from asset managers who are seeking portfolio diversification, to high-net-worth clients who are increasingly looking for exposure to broader crypto use cases, to hedge funds that are largely aiming to profit from the basis between going long the physical and short the future—an arbitrage that reflects the difficulties that still persist in accessing the market today.

Beyond this issue of market fragmentation, we conclude with a look at some of the other main obstacles to further institutional adoption of crypto assets. Alan Cohen, previous senior policy advisor to former SEC Chairman Jay Clayton and former GS Global Head of Compliance, explains how regulators are looking at crypto assets today. Michael Gronager, Co-founder and CEO of blockchain investigations firm Chainalysis, explains what is—and isn’t—included in their analysis that finds that less than 1% of all cryptocurrency activity is illicit. And Dan Guido, Co-founder and CEO of software security firm Trail of Bits, discusses the black swan technological and security scenarios that all investors in the crypto ecosystem should be aware of.
Interview with Michael Novogratz

Michael Novogratz is CEO of Galaxy Digital Holdings Ltd. Below, he discusses the potential for crypto assets and their ability to transform the financial system and beyond.

The views stated herein are those of the interviewee and do not necessarily reflect those of Goldman Sachs.

Allison Nathan: How does Galaxy invest in the crypto universe?

Michael Novogratz: Galaxy Digital grew out of my family office, which operates like a merchant bank, and has become a nearly full-service business for the digital asset and blockchain technology communities. Being involved across the ecosystem is important to us, namely so that we can be positioned to help grow the industry that we believe will transform the way we live and work globally. We own and trade coins, have a large venture business, and invest in the virtual world that will be used not by finance, but by consumers—the metaverse, gaming studios, and non-fungible token (NFT) projects. We believe you learn by being at the frontier and that’s why we started the company—to learn about the crypto space and share that knowledge with our institutional customers as we create the next generation of financial services companies.

Allison Nathan: You’ve been involved in and excited about the crypto space for a while now, but it’s had fits and starts, including the dramatic price rise and collapse in 2017/18. What makes this time different?

Michael Novogratz: 2017/2018 was the first-ever truly global and retail-driven speculative mania. It was blind excitement. It’s not that there are no excesses, knuckleheaded Twitter comments, cheerleading, or tribalism today, but that’s all there was back then. And crypto’s market cap cratered 98.5%. But out of that mania grew a much smarter investor base that took the lessons learned and is more willing to differentiate between the different use cases for crypto—from stores of value to decentralized finance (DeFi) to stablecoins and payment systems. And in turn, the community has built up a more logical investment process.

Importantly, that price downturn didn’t result in a downturn in investments being made in the underlying crypto infrastructure, so the custody and security infrastructure necessary to attract institutions has been built. As a result, we’ve now hit a critical mass of institutional engagement. Everyone from the major banks to PayPal and Square is getting more involved, which is a loud and clear signal that crypto is now an official asset class. There’s still a lot of volatility, so people will wash in and out. But crypto is not going away. And a core group of crypto people see this as—and I quote the Blues Brothers here—“a mission from god”... They will never sell. And because of that, bitcoin and ether can’t go to zero.

Allison Nathan: But can the crypto ecosystem survive if it isn’t intertwined with the traditional financial system?

Michael Novogratz: No. Institutions need to participate because they have most of the money in the world and there’s actually a symbiotic relationship between the two. The advisor model that Galaxy possesses is important because many people don’t have time to learn to become investors. And as traditional financial advisors and asset managers understand the space and become crypto preachers, they bring more people into the tent, which is key for the future of crypto.

That said, payments will be an interesting battleground. The money transfer business is a very high margin one for legacy financial institutions and it’s under threat from new payment systems that are faster, more transparent, and cheaper. Facebook is coming out with their Dollar-based payment system, the Chinese government is coming out with theirs, and stablecoins are gaining traction. At some point, I believe our phones will have crypto wallets that will replace bank accounts. The competition to see who dominates payments is just starting along with the competition between exchanges and derivative markets. So the question is, how fast will banks iterate and compete?

“...a mission from god”... They will never sell. And because of that, bitcoin and ether can’t go to zero.”

Allison Nathan: But will it be bitcoin that’s transformative in payments?

Michael Novogratz: No. Bitcoin isn’t set up to process thousands of transactions per second. Paying for a diet coke with bitcoin would be like paying for it with gold. That won’t happen. But payment rails will be built on other blockchains. Right now, if I want to send money to my sister in Holland, it would be painful, costly, and slow. But soon, I’ll be able to send her a Dollar stablecoin and transferring money will become free. Most of this will be built on the Ethereum network, which is why ethereum prices have been rising. The three biggest moves in the crypto ecosystem—payments, DeFi, and NFTs—are mostly being built on Ethereum, so it’s going to get priced like a network. The more people that use it and the more stuff that gets built on it, the higher the price will ultimately go.

Allison Nathan: What’s the value proposition of bitcoin, then?

Michael Novogratz: Bitcoin is a really convenient way to store value. One of the main reasons people have gotten excited about bitcoin recently is that they’re worried that we currently have an unsustainable balance of monetary and fiscal policy...
that will eventually set off an inflationary spiral. And that worry isn’t going away anytime soon. More and more Americans are in favor of paying for college for people whose families earn less than $100k annually. President Biden just gave half of the $1.9tn fiscal package directly to people who needed it, which was very well-received. Some version of universal basic income (UBI) is coming; it may not be called UBI, but capital will be taxed and given to labor. None of that is fiscally prudent, but there’s no political imperative to say stop spending money. Even before COVID-19, deficits were bad, but now they’re insane. And monetary policymakers are financing everything the government wants to spend, not just in the US but all over the world. So the main reason everyone got into bitcoin is the same reason they got into gold—the current macro backdrop is tailor-made for it. And, as long as that macro and political backdrop persists and crypto remains in the adoption cycle, it’s crazy to get out.

The three biggest moves in the crypto ecosystem—payments, DeFi, and NFTs—are mostly being built on Ethereum, so it’s going to get priced like a network. The more people that use it, the more stuff that gets built on it, and the higher the price will ultimately go.”

**Allison Nathan: What do you make about the rise of Dogecoin and other meme coins?**

**Michael Novogratz:** Dogecoin is a very speculative asset, much more so than bitcoin. It likely doesn’t have long-term legs because no institution is buying it and at some point, retail will lose interest. Dogecoin started as a joke and grew for two reasons. First and foremost is tribalism in the investing community. It’s the same thing we saw with the rise in GameStop, which was driven by a young community of investors who have been empowered as financial players through trading apps and social media platforms. Second, value is showing up in new places because the government is printing a lot of money. It’s important to keep that in mind when thinking about some crypto assets and equities like GameStop that have short-term potential but no long-term viability.

**Allison Nathan: What would make enthusiasm for the asset class diminish?**

**Michael Novogratz:** I am not sure what could dent enthusiasm for the broader ecosystem at this point. But, at least for bitcoin, the biggest risk in this cycle is, in the words of Ray Dalio, a beautiful de-leveraging. If the Fed successfully taps the brakes, pulls back liquidity, and slows the economy down just enough to ensure inflation doesn’t run away and deficits come down, then the impetus for having a store of value will fall. But this is the hardest macro environment policymakers have ever dealt with, and only a tiny window exists to get it right. And even if they do, bitcoin won’t just collapse into oblivion. Why has gold been a mediocre asset to own this year and bitcoin’s generally been a great one? Because gold isn’t in the adoption cycle. Bitcoin is.

Interview with Nouriel Roubini

Nouriel Roubini is a professor of economics at New York University’s Stern School of Business. He is CEO of Roubini Macro Associates, LLC, a global macroeconomic consultancy firm. Below, he discusses his skepticism about the value of cryptocurrencies and their ability to radically transform the financial system.

The views stated herein are those of the interviewee and do not necessarily reflect those of Goldman Sachs.

Interview with Nouriel Roubini

Allison Nathan: Why do you think bitcoin and other cryptocurrencies are in a bubble?

Nouriel Roubini: To start, calling them currencies is a misnomer. Currencies must have four qualities: they must be a unit of account, a means of payment, a stable store of value, and act as a single numeraire. Bitcoin and most other cryptocurrencies have none of these features. It’s not a unit of account; nothing is priced in bitcoin. It’s not a scalable means of payment; the Bitcoin network can only complete seven transactions per second, versus the Visa network that can conduct 65,000. It’s not a stable store of value for goods and services; even the crypto conferences I’ve attended don’t accept bitcoin for payment because the price volatility could wipe out their profit margin overnight. And the crypto universe doesn’t offer a single numeraire in which the prices of different items can be denominated because there are thousands of tokens and thus limited price transparency. Even the Flintstones had a more sophisticated system by using shells as a single numeraire to compare the price of different goods.

Bitcoin and other cryptocurrencies also aren’t assets. Assets have some cash flow or utility that can be used to determine their fundamental value. A stock provides dividends that can be discounted to arrive at a valuation. Bonds provide a coupon, loans provide interest, and real estate provides rent or housing services. Commodities like oil and copper can be used directly in different ways. And gold is used in industry, jewelry, and has historically been a stable store of value against a variety of tail risks, including inflation, currency debasement, financial crisis, and political and geopolitical risk. Bitcoin and other cryptocurrencies have no income or utility, so there’s just no way to arrive at a fundamental value. A bubble occurs when the price of something is way above its fundamental value. But we can’t even determine the fundamental value of these cryptocurrencies, and yet their prices have run up dramatically. In that sense, this looks like a bubble to me.

Allison Nathan: Why are more institutions interested in getting involved in cryptocurrencies if they are in a bubble, and will this help stabilize and credentialize the market?

Nouriel Roubini: Given the large trading volumes, it pays to facilitate trading activity, custodial services, etc. But do institutional investors really want to get more involved? Maybe some do, but I don’t see it becoming mainstream. There’s an argument that because only a fraction of institutional money is currently invested in bitcoin relative to gold, the price of bitcoin could go to the moon as a result of asset re-allocation from gold. But I’m doubtful institutions want exposure to an asset that can drop by 15% overnight. There’s also always the risk that something else backed by real assets might end up completely replacing bitcoin as an alternative store of value. Bitcoin could disappear one day, but gold won’t. And the idea of corporate treasurers allocating to crypto assets is totally crazy. No serious company would do that because treasury accounts must be invested in stable assets with minimal risk, even if they provide a very low return. Any treasurer who invests in something that falls 15% in value overnight will be fired. Sure, Elon Musk can do it because he’s the boss, although he’s since backtracked somewhat on bitcoin due to environmental concerns. But few other people are in that position.

Allison Nathan: But didn’t gold also have highly volatile periods before it matured as an institutional asset?

Nouriel Roubini: While gold has experienced periods of volatility, a set of economic fundamentals generally drove those price swings. Gold rises with inflation and inflation expectations because it’s an inflation hedge, and it falls when the Fed tightens monetary policy and rates rise, not just in nominal but also in real terms, for the same reason. Gold is inversely related to the value of the Dollar, because a falling Dollar leads to higher commodity production costs and prices, including for gold. When there’s serious political or geopolitical risk or a financial crisis, the value of gold rises because it serves as a safe haven asset, as does the Swiss Franc, the Japanese Yen and US Treasuries. A whole set of variables can be used to determine the demand for gold relative to its supply, which makes it possible to establish a fundamental price. In contrast, the prices of bitcoin and other cryptos don’t have a consistent relationship with economic fundamentals that explains their volatility or suggests it will eventually subside.

Allison Nathan: But couldn’t bitcoin serve as an inflation hedge similar to gold given that it doesn’t have exposure to currency debasement?

Nouriel Roubini: It’s true that inflation and inflation expectations have moved higher, the Dollar has started to weaken, and US breakevens are now well above 2%. But while the price of gold and other inflation hedges has reflected these shifts to a limited extent, at their peak, bitcoin’s price had increased by more than tenfold from a low of $5K to more than $60K in a year. That can’t be explained by a fear of currency debasement, because if there was really such a strong worry, gold and other assets like TIPS would likely have rallied more. So, something else must account for the rise in bitcoin and other crypto prices.

Does bitcoin offer protection against debasement? At least among the cryptos, it can’t be debased because a cryptographic rule determines the increase in supply and caps total supply at 21mn. But just because something is scarce doesn’t mean it has fundamental value. It’s not difficult to create something with limited supply, and there’s no reason artificial scarcity is...
valuable in and of itself. Beyond bitcoin, the supply of most cryptocurrencies is determined by a bunch of whales and insiders based on random rules that can be used to increase supply ad-hoc. And their supply has actually increased at a much faster rate than the balance sheet of any central bank given the proliferation of the number of coins. Scarcity also doesn’t make something a reliable store of value. It took a hundred years for the value of the Dollar to fall by 90% in real terms. In 2018, it only took 12 months for thousands of cryptocurrencies to lose the same amount of value, and even bitcoin fell by more than 80%. That’s currency debasement. Bitcoin isn’t even a reliable hedge for risk-off events, let alone inflation shocks. It’s actually highly pro-cyclical. During the peak of the COVID-19 shock in early 2020, US equities fell by about 35%, but bitcoin collapsed by around 50%. Other top 10 crypto currencies fell by even more. In difficult times, crypto assets don’t go up; they go down. If investors want inflation hedges, a wide variety of assets have proven to be good inflation hedges for decades, including commodities and their stocks, gold, TIPS, inflation-adjusted and other forms of inflation-indexed bonds. I do worry that monetized deficits might eventually lead to fiscal dominance and higher inflation. But I wouldn’t recommend bitcoin or other cryptocurrencies to protect against this risk.

Allison Nathan: Nascent technologies are often volatile in their adoption phase. What makes this moment for crypto any different than the early days of the internet?

Nouriel Roubini: More than a decade on from the advent of Bitcoin, it’s nowhere near as transformative as the internet was at a similar stage. The World Wide Web already had around a billion users ten years in. While it’s difficult to know the total number of crypto users today, active users for the most traded coins probably amount to a maximum of a hundred million. Transaction growth for cryptocurrencies has been slower than in the case of the internet, and transaction costs remain very high, with mining revenues as a share of the total volume of transactions still very high. After ten years of the internet, there was email, millions of useful websites and apps, and technologies like the TCP and HTML protocols with broader applications. In the case of cryptocurrencies, there are so-called “dApps”, or decentralized apps, but 75% of dApps are games like CryptoKitties or literally pyramid or Ponzi schemes of one sort or another. And the other 25% are “DEXs”, or decentralized exchanges, that for now have few transactions and little liquidity. So the comparison with the internet just doesn’t ring true.

Allison Nathan: Doesn’t the concept of decentralized ledgers and networks have value, though?

Nouriel Roubini: I am not sure it does, but the reality is that the crypto ecosystem is not decentralized. An oligopoly of miners essentially controls about 70-80% of bitcoin and ether mining. These miners are located in places like China, Russia, and Belarus, which are strategic rivals of the US and have a different rule of law. That’s why the US National Security Council is starting to worry about the risks that could pose for the United States. And 99% of all crypto transactions occur on centralized exchanges. Many crypto currencies also have a concentrated group of core developers who are police, judge, and jury whenever updates to or conflicts over the blockchain arise. Rules assumed to be fixed have been changed in these situations. So the blockchain isn’t even immutable.

There’s some evidence that the ownership of crypto wealth is also highly concentrated. Less than 0.5% of addresses own around 85% of all bitcoin, based on CoinMarketCap data. There’s also evidence that whales holding a large amount of the total supply of bitcoin and other cryptocurrencies actively manipulate their prices. Tons of news articles have detailed active manipulation in chat rooms in the form of pump-and-dump schemes, spoofing, wash trading, front-running, etc. This behavior is much worse than even penny stocks, which suggests a high likelihood of an eventual regulatory crackdown.

Allison Nathan: Does any innovation in the crypto ecosystem look promising to you?

Nouriel Roubini: Not really. The next decade will see radical financial innovation across many dimensions, disrupting the traditional financial system. But it will have nothing to do with cryptocurrencies. Driving this innovation will be a revolution in fintech owing to some combination of AI, machine learning, and the use of the Internet of Things (IoT) to collect big data. Fintech is already transforming payment systems, borrowing and lending, credit allocation, insurance, asset management, and parts of the capital markets. In the context of payment systems, billions of transactions are made every day using AliPay and WeChat Pay in China, M-Pesa in Kenya and most of Sub-Saharan Africa, and Venmo, PayPal, and Square in the United States. These are all great companies that are scalable, secure, and are disrupting financial services. They’re not based on decentralized finance (DeFi), and have nothing to do with crypto or blockchain.

I’ve honestly spent a lot of time looking at this because more and more people are saying that while maybe these aren’t currencies, blockchain technology could be revolutionary. There are now all these buzzwords like “enterprise distributed ledger technology (DLT)” or “corporate blockchain.” But I call most of these projects BINO—“Blockchain In Name Only”. Something truly based on blockchain technology should be public, decentralized, permissionless, and trustless. But looking at DLT and corporate blockchain experiments, almost all of them are private, centralized and permissioned—because a small group of people has the ability to validate transactions—and most are authenticated by a trusted institution.

And even among these projects, few have actually worked. One study looking at 43 applications of blockchain technologies in the non-profit sphere for reasons such as banking the unbanked, giving IDs to refugees, and transferring remittances found that zero actually worked. The fundamental problem with this whole space is that it assumes the idea that technology can create trust. But that’s mission impossible. Resolving the challenge of authenticating ownership or quality requires due diligence and testing. Why should I trust a DLT that says my tomatoes are organic? I trust Whole Foods that actually tests the tomatoes for chemicals. The idea that technology can resolve the question of trust is delusional. So, I’m deeply skeptical that blockchain, DLT, and cryptocurrencies for that matter will be the revolutionary technologies that their proponents suggest.
Zach Pandl argues that institutional investors should treat bitcoin as a macro asset, akin to gold, going through a social adoption phase.

Although bitcoin is now seeing wider institutional adoption, many sophisticated investors still struggle to understand why a digital asset should have any value—much less a market capitalization of more than $500bn. And because of the parabolic price increases and high retail participation, many treat the cryptocurrency phenomenon as a classic speculative mania or “bubble”. Regardless of whether bitcoin will prove to be a good investment over time, this perspective is too narrow. Bitcoin is a medium which is beginning to serve the functions of money—primarily as a “store of value”. Virtually anything can serve this purpose as long as it gains widespread social adoption, and bitcoin has made meaningful progress down that path.

The need for stores of value

To understand bitcoin, it is best to begin with gold. Gold serves a unique function in the global financial system. It is both a useful commodity and a money-like, “store of value” asset. However, unlike conventional money mediums, it is not issued by a government and does not denominate any transactions in goods or assets. In effect, gold serves as an alternative fallback money instrument for adverse states of the world—when investors are unsure about the safety of conventional assets or fiat money in general (e.g. due to the risk of inflation or confiscation). In foreign exchange markets, gold behaves like an “inverse currency”: its price tends to fall when the fundamentals of major currencies improve, and tends to rise when the fundamentals of major currencies worsen. Over time, the most important driver of nominal exchange rates is the relative rate of inflation between two economies. Because gold has a quasi-fixed supply, its nominal value tends to rise at the rate of inflation in major markets. These correlation and store of value properties allow gold to play a very useful diversification role in portfolios.

Originally, gold was likely adopted as a money medium due to its elemental properties. Gold and copper are the only metals which are not greyish in color in their natural state 1, and they have captivated humans since ancient times. Gold is also relatively dense, malleable, and ductile (stretchable), and unlike many other metals it does not tarnish, rust, or corrode. These features have underpinned gold’s use as a money instrument throughout human history.

But the use of gold today has as much to do with inertia as it does with the metal’s physical properties. After all, US Dollar notes are also a store of value, and they are made of paper 2. Money, like language, is a social device—it is closer to a concept than a thing. Money is a social device that facilitates commerce, in much the same way that language is a social device that facilitates other aspects of our lives. It is useful for society to have a type of money that is not issued by a sovereign government. But the specific medium used for that purpose is partly arbitrary. Throughout history, a diverse array of objects has functioned as money, dictated by the demands of place and time—as Bitcoiners and monetary historians are fond of pointing out. Classic examples include the tobacco-based money standards of the early American colonies, and the regular use of mobile phone minutes as money throughout Africa. Gold serves a money function today primarily as an artifact of history, not because it is literally the best possible medium for society’s store of value needs.

Gold plays an important diversification role in portfolios

When inflation accelerated in the mid-20th century and investors sought out options to protect the real value of their assets, gold was the natural choice. At the time, major currencies were pegged to gold via the US Dollar through the Bretton Woods gold exchange standard, and, before the Great Depression, most currencies, as well as most US Treasury notes, were directly backed by gold. The US government provided an official price of gold in Dollars, which changed only twice in the nearly two centuries between the 1790s and 1970s. During the 1960s, under the gold exchange standard, gold trading above its official stated price was the clearest way to observe depreciation pressure on the US Dollar. In short, over much of the post-WWII period, there was a close association between the price of gold, currency stability, and the real value of money—making it the obvious inflation hedge for portfolios.

But the official link between the Dollar and the price of gold was severed 50 years ago when President Nixon ended the convertibility of Dollars into gold in August 1971. As a result, a generation of asset holders have grown up in a world without a tight connection between gold and money. So when the need for a store of value asset arises, could it be that they reach for something else?

Gold for the digital generation

This is where bitcoin comes in. Any alternative medium would need to be secure, privately held, have a fixed or quasi-fixed supply, and be transferable, ideally outside the traditional payments system. In our modern globalized society, where a substantial portion of social interaction and commerce occurs online (especially among younger people), it may also need to be digital. But, most importantly, it would need to have the potential for widespread social adoption—anything can be money, as long as it has that. Bitcoin is therefore a plausible alternative.

1 Gold’s periodic symbol Au comes from the Latin word aurum, meaning “shining dawn.”
2 Technically a 75% cotton-based and 25% linen-based material.

alternative store of value medium to gold and, at the moment, the best candidate among cryptocurrencies with a similar structure because of its broader social adoption (i.e. its "name brand").

In equilibrium, a store of value as volatile as bitcoin would not be very useful. But cryptocurrencies are in their infancy; it is better to think of today’s prices as reflecting some probability that bitcoin or another coin/token could achieve greater adoption in the future, at which time its price could be extremely high. Therefore, small changes in those probabilities can result in high price volatility today. Bitcoin investors are speculating that it will eventually achieve near-universal acceptance as a non-sovereign money, with high returns (and high volatility) along the way.

The critical ingredient to bitcoin’s success—widespread social adoption—has now crossed many notable thresholds: Tesla, the sixth largest company in the S&P 500, is carrying bitcoin on its balance sheet; storied macro hedge fund Brevan Howard has begun investing in cryptocurrencies; and Coinbase is now listed on the Nasdaq. Other blockchain networks, especially Ethereum, are developing decentralized banking platforms, Facebook is expected to introduce its stablecoin Diem later this year, and many central banks are exploring distributed ledger technology for their own digital currencies. Whether bitcoin will succeed as a store of value in the long run remains an open question—and its consumption of real resources may be a headwind over time—but for now social adoption of cryptocurrencies appears to be moving forward.

**Bitcoin as a macro asset**

Bitcoin has also matured enough that its price behavior resembles that of other macro assets. For example, at its March 17th meeting, the Federal Reserve said that most policymakers did not expect to raise interest rates until after 2023—later than financial markets had expected. Macro assets reacted in the conventional way to a “dovish policy shock”: shorter-maturity Treasury yields declined, the yield curve steepened, the Dollar fell, and stock prices increased. Bitcoin rose, just like gold, but with about four times the volatility.

Investors should treat bitcoin in this way. Gold is a *commodity* that serves a *money* function and behaves like a *currency*. Bitcoin is exactly the same, even though it is a digital commodity created through cryptography, rather than a physical commodity found in the Earth’s crust. From a markets standpoint, the main difference between the two assets is that bitcoin is going through a one-time social adoption phase—which may succeed or fail. When social adoption is rising, bitcoin should offer superior returns compared to gold. When social adoption is declining (e.g. due to adverse regulatory changes), bitcoin will likely offer inferior returns compared to gold. Because of the speculative nature of the asset class and high uncertainty around valuation, investors should be prepared for prices to overshoot fundamentals in both directions. While bitcoin has generally appreciated in value over time, there have already been several waves of speculative excess followed by large drawdowns.

Technological issues aside, the current macroeconomic outlook appears favorable for store of value assets, whether physical or digital. The Federal Reserve has adopted a more ambitious labor market goal of “broad and inclusive” full employment, and seems more tolerant of above-target inflation than in the recent past. Our economists expect real cash yields to remain negative across developed market economies for a number of years to come. Equity market multiples are at historic highs. Many developing countries will struggle with the fiscal hangover from the COVID-19 crisis for years to come. In this environment, unless investors can find other sources of real returns, demand for assets that protect purchasing power should remain high.

**Low real interest rates should support high demand for “store of value” assets over the next several years**

Jeff Currie argues that cryptos are a new class of asset that derive their value from the information being verified and the size and growth of their networks, but legal challenges loom large.

The term “cryptocurrencies”—which most people take to mean that crypto assets act as a digital medium of exchange, like fiat currency—is fundamentally misleading when it comes to assessing the value of these assets. Indeed, the blockchain that underlies bitcoin was not designed to replace a fiat currency—it is a trusted peer-to-peer payments network. As a cryptographic algorithm generates the proof that the payment was correctly executed, no third party is needed to verify the transaction. The blockchain and its native coin were therefore designed to replace the banking system and others like insurance that require a trusted intermediary today, not the Dollar. In that sense, the blockchain is differentiated from other “digital” transactional mechanisms such as PayPal, which is dependent upon the banking system to prevent fraud like double-spending. In order to be trustworthy, the system needed to create an asset that had no liabilities or contingent claims, which can only be a real asset just like a commodity. And to achieve that, blockchain technologies used scarcity in natural resources—oil, gas, coal, uranium and hydro—through ever-increasing computational-power consumption to “mine” a bit version of a natural resource.

From this perspective, the intrinsic value of the network is the trustworthy information that the blockchain produces through its mining process, and the coins native to the network are required to unlock this trusted information, and make it tradeable and fungible. It’s therefore impossible to say that the network has value and a role in society without saying that the coin does too. And the value of the coin is dependent upon the value and growth of the network.

That said, because the network is decentralized and anonymous, legal challenges facing future growth for crypto assets loom large. Coins trying to displace the Dollar run headlong into anti-money laundering laws (AML), as exemplified by the recent ransoms demanded in bitcoin from the Colonial Pipeline operator and the Irish Health service. Regulators can impede the use of crypto assets as a substitute for the Dollar or other currencies by making them non-convertible. And to achieve that, blockchain technologies used scarcity in natural resources—oil, gas, coal, uranium and hydro—through ever-increasing computational-power consumption to “mine” a bit version of a natural resource.

Transactions drive value, creating a risk-on asset
Crypto doesn’t trade like gold and nor should it. Using any standard valuation method, transactions or expected transactions on the network are the key determinant of network value. The more transactions the blockchain can verify, the greater the network value. Transaction volumes and the demand for commodified information are roughly correlated with the business cycle; thus, crypto assets should trade as pro-cyclical risk-on assets as they have for the past decade. Gold and bitcoin are therefore not competing assets as is commonly misunderstood, and can instead co-exist.

Derived demand leaves the holder of the commodity exposed to the risk of the network becoming obsolete—a lesson that holders of oil reserves are now learning with decarbonization accelerating the decline of the transportation network, and, in turn damaging oil demand. Likewise, bitcoin owners face accelerated network decay risk from a competing network, backed by a new cryptocurrency.

As the demand for gold is not dependent on a network, it will ultimately outlive oil and bitcoin—gold entropy lies at the unit, not the network, level. Indeed, most stores of value that are used as defensive assets—like gold, diamonds and collectibles—don’t have derived demand and therefore only face unit-level entropy risk. This is what makes them defensive. The world can fall apart around them and they preserve their value. And while they don’t have derived demand, they do have other uses that establish their value, i.e. gold is used for jewelry and as a store of value.

The network creates the value, unlike other commodities
Unlike other commodities, coins derive their entire value from the network. A bitcoin has no value outside of its network as it is native to the Bitcoin blockchain. The value of oil is also largely derived from the transportation network that it fuels, but at least oil can be burned to create heat outside of this network. At the other extreme, gold doesn’t require a network at all.

Non-currency crypto assets are starting to dominate use
Transactions on the Ethereum blockchain vs. transactions on the Bitcoin blockchain, ratio (lhs); Number of active nodes on Ethereum network vs. active nodes on Bitcoin network, ratio (rhs)

Source: Bloomberg, Goldman Sachs GIR.
crypto investments will need to be held in the form of futures contracts, not physically, if they are to serve as stores of value. Crypto assets aren’t digital oil, either, as they are not non-durable consumables and can therefore be used again. This durability makes them a store of value, provided this demand doesn’t disrupt network flows. The crypto assets that have the greatest utility are also likely to be the dominant stores of value—the high utility reduces the carry costs.

Paid networks—and hence cryptocurrencies—are pro-cyclical, as greater use drives value

So what is crypto? A powerful networking effect

The network provides crypto an extremely powerful networking externality that no other commodity possesses. The operators—miners, exchanges and developers—are all paid in the native coin, making them fully vested in its success. Similarly, users—merchants, investors and speculators—are also fully vested. This gives bitcoin holders an incentive to accommodate purchases of their own products in bitcoin, which in turn, creates more demand for the coins they already own. Similarly, ether holders have an incentive to build apps and other products on the Ethereum network to increase the value of their coins.

Because the coin holders have a stake in the network, speculation spurs adoption; even during bust periods, coin holders are motivated to work to create the next new boom. After the dot-com bust, the shareholders had no commodity to promote. In crypto assets, even when prices collapse, the coin holders have a commodity to promote. They will always live for another boom, like an oil wildcatter.

It’s all about information

As the value of the coin is dependent on the value of the trustworthy information, blockchain technology has gravitated toward those industries where trust is most essential—finance, law and medicine. For the Bitcoin blockchain, this information is the record of every balance sheet in the network, and the transactions between them—originally the role of banks. In the case of a smart contract—a piece of code that executes according to a pre-set rule—on Ethereum, both the terms of that contract (the code) and the state of the contract (executed or not) are the information validated on the Ethereum blockchain. As a result, the counterparty in the contract cannot claim a transfer of funds without the network forming a consensus that the contract was indeed executed. In our view, the most valuable crypto assets will be those that help verify the most critical information in the economy.

Over time, the decentralized nature of the network will diminish concerns about storing personal data on the blockchain. One’s digital profile could contain personal data including asset ownership, medical history and even IP rights. Since this information is immutable—it cannot be changed without consensus—the trusted information can then be tokenized and traded. A blockchain platform like Ethereum could potentially become a large market for vendors of trusted information, like Amazon is for consumer goods today.

Crypto beyond this boom and bust cycle

By many measures—Metcalf’s Law or Network Value to Transactions (NVT) ratio—crypto assets are in bubble territory. But does the demand for “commodified information” create enough economic value at a low enough cost to be scaled up in the long run? If the legal system accommodates these assets, we believe so. While many overvalued networks exist, a few will likely emerge as long-term winners in the next stage of the digital economy, just as the tech titans of today emerged from the dot-com boom and bust. This transformation is happening now—there are already an estimated 21.2 million owners of cryptocurrencies in the US alone. However, technological, environmental and legal challenges still loom large.

Ethereum 2.0 is expected to ramp up capacity to 3,000 transactions per second (tps), while sharding—which will scale Ethereum 2.0’s Proof of Stake (PoS) system through parallel verification of transactions—has the potential to raise capacity to as much as 100,000 tps. For context, Visa has the capacity to process up to 65,000 tps but typically executes around 2,000 tps. PoS intends to have validators stake the now scarce and valuable coins to incentivize good behavior instead of having miners expend energy to mine new blocks into existence, as under Proof of Work, making crypto assets more ESG friendly. PoS also can significantly boost computational time in terms of transactions per second, which will further incentivize technological adoption. Ironically, this is likely where the value of and demand for bitcoin will come from—being used as the scarce resource to make the PoS system work instead of natural resources.

While overcoming the economic challenges will likely be manageable, the legal challenges are the largest for many crypto assets. And this past week was challenging for crypto assets with confirmation that the 75 bitcoin ransom over the Colonial Pipeline was actually paid. This is a reminder that cryptocurrencies still facilitate criminal activities that have large social costs. For Ethereum, new companies which aim to disrupt finance, law or medicine by integrating information stored on the platform into their algorithms are likely to run into problems with being legally recognized. If crypto assets are to survive and grow to their fullest potential, they need to define some concept of “sufficiently decentralized” that will satisfy regulators; otherwise, the technologies will soon run out of uses.

Michael Sonnenshein is CEO at Grayscale Investments. Below, he discusses the evolution of the digital asset ecosystem and the factors behind rising institutional interest in the space.

The views stated herein are those of the interviewee and do not necessarily reflect those of Goldman Sachs.

Interview with Michael Sonnenshein

Michael Sonnenshein is CEO at Grayscale Investments. Below, he discusses the evolution of the digital asset ecosystem and the factors behind rising institutional interest in the space.

The views stated herein are those of the interviewee and do not necessarily reflect those of Goldman Sachs.

**Allison Nathan:** How does Grayscale and its parent company, Digital Currency Group, engage in the digital asset universe?

**Michael Sonnenshein:** Grayscale Investments is a digital currency asset manager with AUM of about $45 billion today spread across a family of 14 unique investment products, the largest of which is the Grayscale Bitcoin Trust.

The Grayscale business model is predicated on providing investors access and exposure to digital currencies while avoiding the challenges involved in buying and safely storing digital currencies themselves. Our parent company, Digital Currency Group, is a conglomerate that seeks to invest in, build, and purchase businesses related to digital currency and blockchain technology, and has invested in about 170 digital currency/blockchain-related businesses in over 40 countries.

**Allison Nathan:** How do your products differ from a crypto ETF, which has yet to gain regulatory approval in the US?

**Michael Sonnenshein:** All of our products are passive, long-only funds that are directly invested in the referenced digital asset for each product. So a $100 investment in the Grayscale Bitcoin Trust is backed by $100 worth of bitcoin, which is bought in the market and then stored in cold storage with a qualified custodian that is a fiduciary under New York state banking laws, and who also insures the assets. Today, six out of the 14 funds are also publicly quoted and traded on the OTCQX markets, where the ADRs of many foreign companies trade. These represent a secondary market that in some ways mimic the attributes of an ETF because they trade every day, but they are not ETFs. The two largest differences between them and an ETF are, one, they do not trade on a national securities exchange, like NYSE or NASDAQ, and two, they do not have ongoing creation and redemptions like ETFs. So they operate more like a closed-end offering than an ETF.

**Allison Nathan:** You have a bird’s eye view on the digital asset investor base. How has it evolved?

**Michael Sonnenshein:** In 2013/14, when I got my start in the digital currency space, only Silicon Valley VCs, and maybe some forward-thinking family offices, were speaking about digital assets. Over time, interest in digital assets began to trickle down to retail investors who were gaining access to crypto through trading platforms and order books. And, more recently, the most meaningful shift has been increased interest from institutional investors. Several years ago, digital assets were generally considered a taboo asset class among institutional investors because of perceived reputational risks, regulatory concerns and a view that engaging in digital assets was just too much of a departure from the other strategies they typically employ. Today, not only is there a general appreciation amongst all investors, including the institutional community, that digital assets are here to stay, but also all of those preconceived notions have been shrugged off. We no longer hear concerns about nefarious activity on the blockchain. We no longer hear about reputational concerns; investors now want their fiduciaries to participate in crypto. And we no longer hear concerns about regulatory risk; regulators have provided enough clarity for investors to feel comfortable participating.

Over just the last 12 to 18 months, the asset class has really turned the corner as some well-known and experienced investors have publicly come out in support of crypto, corporations have begun to allocate to crypto on their balance sheet as a reserve asset, and participation from legacy financial institutions has materially increased. All of these developments signal that, across the spectrum, the investment community wants to participate in the crypto ecosystem, and is as smart as ever on the asset class. I have yet to find somebody who has really done their homework on crypto assets that isn’t truly amazed by the potential for the asset class.

That being said, in the same way that not every investment opportunity will be right for all investors, digital assets are not necessarily the best fit for all institutions. It’s also important to remember that the asset class is only 10-12 years old and so is still in its very early days. But we are now at a point where the crypto market is as robust as it’s ever been in terms of being a two-sided market, having the ability to engage in derivatives, lending and borrowing, and offering many of the same kinds of products as traditional asset classes.

**Allison Nathan:** Why do institutional investors want to be involved in the market?

**Michael Sonnenshein:** The potential for significant upside is certainly an attraction. But more than anything, investors realize the significant diversification benefit of adding crypto to their portfolios, which can help them achieve higher risk-adjusted returns. As policymakers have injected substantial stimulus into the financial system in order to jumpstart the economy from the COVID-related slowdown, investors have become increasingly attracted to the finite quality of assets like bitcoin—which is verifiably scarce—as a way to hedge against inflation and currency debasement. Investors are starting to move out of assets like gold, which historically have served as stores of value or inflation hedges, as they realize that assets like bitcoin can also serve those roles in their portfolios.

**Allison Nathan:** But given the short history of bitcoin/digital assets, isn’t it too soon to conclude that these assets provide diversification benefits or are a hedge against inflation, especially since they seemed to act more like risky assets during the depths of the pandemic recession?

**Michael Sonnenshein:** We’ve found that during some macro shocks, like the devaluation of the renminbi in 2015 or the unexpected Brexit vote in 2016, crypto outperformed. However, during periods of broad-based selloffs or de-leveraging, like we saw in March 2020 when COVID-19 brought the global economy to a grinding halt, nothing was safe from what was taking place in the system. Everything sold off—bonds, currencies, equities,
and crypto. But crypto snapped back much faster and more significantly than other asset classes over the course of 2020. After probably the hundredth time of pronouncing crypto “dead”, that resiliency and staying power has solidified for a lot of investors that this is a space they want to be in.

Allison Nathan: But can bitcoin survive as a store of value since it has no other uses—compared to gold that is used for jewelry, art, wine, etc.—which could temper its volatility and put a floor on its value?

Michael Sonnenshein: People have largely left behind the idea that bitcoin needs to be used in everyday commerce in order to be successful, and since it hasn’t yet replaced the Dollar nor am I yet buying my latte with it, it has failed. Again, it’s important to drive home the notion that we are still in the early days of the development of crypto assets and use cases for them. Today, the developed world use case for bitcoin is primarily as a digital store of value that is more suitable to today’s digital world compared to the physical world in which gold may have historically served a better purpose.

Many investors also think of digital asset exposure as an early stage technology investment or as a conduit to the next generation of payment systems and the way in which value may be moved around the world, potentially disrupting remittance networks, cross border payments, etc. But they have the potential to unlock all kinds of other use cases, including areas like microfinancing and micropayments, and leveraging the underlying blockchain technology for commerce, shipping, manufacturing, etc. This technology is truly the most secure and most widely utilized consensus mechanism the world has ever had. And when you think about how powerful consensus can be, we’re not yet anywhere close to utilizing the full capabilities of what the protocol may offer.

Allison Nathan: But isn’t it now well-known that transaction speeds on the Bitcoin blockchain are too slow for it to be useful in the payment system and other commercial uses?

Michael Sonnenshein: You’re right to call out that one of the flaws of Bitcoin is its relatively slow transaction speed. The transactional nature of bitcoin is akin to what you see on Black Friday when many payment networks are bogged down because so many people are shopping and using their credit cards. But slower-than-desirable transaction speeds are also a sign of Bitcoin’s success; the quantity of transactions transpiring on the network was never conceived to be as high as it is today. A variety of efforts have been and are underway to challenge that attribute, and I believe we will continue to find ways to increase transactional throughput.

Allison Nathan: There are already some offshoots of the Bitcoin blockchain that improve upon this flaw. So isn’t it likely that improvements won’t be captured by bitcoin itself, but by another crypto asset?

Michael Sonnenshein: Bitcoin is an open source protocol, which means that people are able to take its source code, copy it over, tweak one attribute, and then launch it as a new digital currency. Some of those currencies, like bitcoin cash, have had staying power and have developed a real user base. That said, the success of one crypto asset over another really boils down to the value of the network built into them. Today, bitcoin has a $700bn market cap, which represents 700 billion dollars of switching costs that would need to be monetized for users to move from bitcoin to something else. Bitcoin’s open source nature provides reassurance that over time as it is challenged, it will integrate new and better features that prevent it from becoming the Myspace to an eventual Facebook.

Allison Nathan: Do you hear institutional investors expressing concerns over the high concentration of crypto holdings or the environmental aspects of mining?

Michael Sonnenshein: There is certainly concentration within the crypto ecosystem among a relatively small number of entities, but that’s not unique to crypto. And we do sometimes hear concerns about the energy consumption of bitcoin miners, but there’s quite a lot of misinformation out there around this. While mining is very energy intensive, it is extremely competitive, and one way that miners can beat out others for mining rewards is to utilize the lowest cost energy. So miners have moved to lower-cost renewable energy sources as much as possible, including solar, wind, hydro, etc.

Allison Nathan: So what are the remaining roadblocks to further institutional adoption and how likely are they to be overcome?

Michael Sonnenshein: The biggest obstacles primarily relate to the plumbing around crypto assets, and the remaining gap between the crypto asset ecosystem and the traditional financial system, but both are actively being addressed. The underpinnings of the crypto ecosystem are still maturing, but tremendous work is underway in terms of improving order management systems, tax lot reporting, algorithms, application programming interfaces (APIs), custodial solutions, and all of the nuts and bolts that digital assets need to thrive. Investors also still can’t access digital assets as easily—or, for the most part, through the same channels—as they do traditional instruments. Recent and future potential developments that bridge the gap between these two ecosystems, such as being able to buy crypto through your prime broker or leveraging a bitcoin ETF, will go a long way in enabling greater participation in digital assets.

Allison Nathan: How much of the interest in digital assets is now being directed beyond bitcoin to other cryptos?

Michael Sonnenshein: There is a meaningful bid for other digital assets from investors who appreciate not only the diversification benefits from owning crypto as an asset class, but also the benefits of diversifying their crypto allocation. As investors have seen the advent of new use cases on top of blockchain like Ethereum, whether that be the proliferation of decentralized finance (DeFi), non-fungible tokens (NFTs), etc., they have increasingly moved beyond just allocating to bitcoin and instead are seeking exposure to the entire ecosystem.

Allison Nathan: Dogecoin: a blessing or a curse for cryptos?

Michael Sonnenshein: Dogecoin is a demonstration of just how easy it is to create a digital asset. It, along with a slew of other digital assets, was created by enthusiasts basically for fun. That drills home the point that it’s important for investors to scrutinize use cases and whether the asset is viable and has the potential to gain real world traction by solving a real world problem versus a solution in search of a problem that may not exist.
What is a digital store of value?

Mikhail Sprogis and Jeff Currie argue that other cryptocurrencies besides bitcoin are better positioned to become the dominant digital store of value.

Based on emerging blockchain technology that has the power to disrupt global finance, yet with limited clear use today, bitcoin has been labeled a solution looking for a problem. Many investors now view bitcoin as a digital store of value, comparable to gold, housing, or fine wine. But all true stores of value in history have provided either income or utility, and bitcoin currently provides no income and only very modest utility.

However, unlike bitcoin, several other crypto assets have clear economic rationales behind their creation. Bitcoin’s first-mover advantage is also fragile; crypto remains a nascent field with shifting technology and consumer preferences, and networks that fail to adjust quickly could lose their leadership. We therefore see a high likelihood that bitcoin will eventually lose its crown as the dominant digital store of value to another cryptocurrency with greater practical use and technological agility. Ether looks like the most likely candidate today to overtake bitcoin, but that outcome is far from certain.

What is a store of value?

A store of value is anything that preserves its value over time. While financial stores of value like equities and bonds hold their value because they produce a given cash flow, yield is not a prerequisite for value. Art, wine, gold, and non-yielding currencies are widely used as stores of value too. Yet all of these non-yielding assets have a clear material use besides being stores of value. This usefulness generates a “convenience yield”—the incentive for people to own them—that reflects both the utility a consumer derives from using these assets and the relative scarcity of that utility—a fact captured by Adam Smith’s famous Diamond-Water paradox.

We place assets on a continuum across time by their store of value properties. We identify stores of future value, like financial assets that offer the owner the right to future yields or the promise of growing value over time, stores of present value, like consumable commodities such as oil and grains for which the utility of driving and eating today imparts a convenience yield, and stores of past value, like gold, art or even housing in which the assets store value generated in the past because of their duration.

Value always stems from use

The key to stores of past value like gold and houses is that someone demanded these assets in the past and placed value in them by exchanging something of value, usually currency, for them. Indeed, all important non-yielding stores of value developed real uses before becoming investment assets. For instance, gold was first used as jewelry to signal permanence, commitment or immortality. The economic problem was a need to signal permanence, and gold’s durable and inert elemental properties solved that problem. Given the state of technology at the time, gold was the only solution for this problem, which explains why so many societies adopted it for this use.

Economic value is created when marginal benefit exceeds marginal cost, and crypto fails this test

And when societies began to conquer each other and needed a means to standardize international trade, gold was the natural choice to solve this economic problem as most societies already owned gold and it was divisible. Real use is important for stores of value because consumption demand tends to be price-sensitive and therefore provides some offset to fluctuations in investment demand, tempering price volatility. For example, jewelry demand is the swing factor in the gold market, falling when investment demand for gold pushes prices higher, and vice versa.

Ether beats bitcoin as a store of value

Given the importance of real uses in determining store of value, ether has high chance of overtaking bitcoin as the dominant digital store of value. The Ethereum ecosystem supports smart contracts and provides developers a way to create new applications on its platform. Most decentralized finance (DeFi) applications are being built on the Ethereum network, and most non-fungible tokens (NFTs) issued today are purchased using ether. The greater number of transactions in ether versus bitcoin reflects this dominance. As cryptocurrency use in DeFi and NFTs becomes more widespread, ether will build its own first-mover advantage in applied crypto technology.

Ethereum can also be used to store almost any information securely and privately on a decentralized ledger. And this information can be tokenized and traded. This means that the Ethereum platform has the potential to become a large market for trusted information. We are seeing glimpses of that today with the sale of digital art and collectibles online through the use of NFTs. But this is a tiny peek at its actual practical uses. For example, individuals can store and sell their medical data through Ethereum to pharma research companies. A digital profile on Ethereum could contain personal data including asset ownership, medical history and even IP rights. Ethereum also has the benefit of running on a decentralized global server base rather than a centralized one like Amazon or Microsoft, possibly providing a solution to concerns about sharing personal data.

Goldman Sachs Global Investment Research
A major argument in favor of bitcoin as a store of value is its limited supply. But demand, not scarcity, drives the success of stores of value. No other store of value has a fixed supply. Gold supply has grown nearly ~2% pa for centuries, and it has remained an accepted store of value. Plenty of scarce elements like osmium are not stores of value. In fact, a fixed and limited supply risks driving up price volatility by incentivizing hoarding and forcing new buyers to outbid existing holders, potentially creating financial bubbles. More important than having a limited supply to preserve value is having a low risk of dramatic and unpredictable increases in new supply. And ether, for which the total supply is not capped, but annual supply growth is, meets this criterion.

**Fast-moving technologies break first-mover advantage**

The most common argument in favor of bitcoin maintaining its dominance over other cryptocurrencies is its first-mover advantage and large user base. But history has shown that in an industry with fast-changing technology and growing demand, a first-mover advantage is difficult to maintain. If an incumbent fails to adjust to shifting consumer preferences or competitors’ technological advances, they may lose their dominant position. Think of Myspace and Facebook, Netscape and Internet Explorer or Yahoo and Google.

For crypto networks themselves, active user numbers have been very volatile. During 2017/18, Ethereum was able to gain an active user base that was 80% the size of Bitcoin’s within one year. Ethereum’s governance structure, with a central developer team driving new proposals, may be best suited for today’s dynamic environment in which crypto technology is changing rapidly and systems that fail to upgrade quickly can become obsolete.

Indeed, Ethereum is undergoing much more rapid upgrades to its protocol than Bitcoin. Namely, Ethereum is currently transitioning from a Proof of Work (PoW) to a Proof of Stake (PoS) verification method. Proof of Stake has the advantage of dramatically increasing the energy efficiency of the system as it rewards miners based on the amount of ether holdings they choose to stake rather than their processing capacity, which will end the electricity-burning race for miner rewards. Bitcoin’s energy consumption is already the size of the Netherlands and could double if bitcoin prices rise to $100,000. This makes bitcoin investment challenging from an ESG perspective.

While PoS protocols raise security concerns due to the need for trusted supervisors in the verification process, Bitcoin is also not 100% secure. Four large Chinese mining pools control almost 60% of bitcoin supply and could in theory collude to verify a fake transaction. Ethereum too faces many risks and its ascendance to dominance is by no means guaranteed. For instance, if the **Ethereum 2.0 upgrade** is delayed, developers may choose to move to competing platforms. Equally, Bitcoin’s usability can potentially be improved with the introduction of the Lightning Network, a change of protocol to support smart contracts and a shift to PoS. All cryptocurrencies remain in early days with fast-changing technology and volatile user bases.

**High vol is here to stay until real use drives value**

The key difference between the current rally in crypto and the crypto bull market of 2017/18 is the presence of institutional investors—a sign that financial markets are starting to embrace crypto assets. But bitcoin’s volatility has remained persistently high, with prices falling 30% in one day in just this past week. Such volatility is unlikely to abate until bitcoin has an underlying real, economic use independent of price to smooth out periods of selling pressure. Indeed, more recently, institutional participation has slowed as reflected in lower **inflows** into crypto ETFs, while the outperformance of altcoins indicate that retail activity has once again taken center stage. This shift from institutional adoption to increasing retail speculation is creating a market that is increasingly comparable to that of 2017/18, increasing the risk of a material correction. Only real demand that solves an economic problem will end this volatility and usher in a new mature era for crypto—one based upon economics rather than upon speculation.

The role of crypto in balanced portfolios

Christian Mueller-Glissmann argues that the short and volatile history of bitcoin makes it difficult to assess how much of a beneficial role it could play in multi-asset portfolios.

An important question both for asset allocators and for those assessing the prospect of further investor adoption of cryptocurrencies is how they fit into a multi-asset portfolio. In recent years, balanced portfolios have become unbalanced as low bond yields have provided less of a buffer against equity drawdowns and as the risk of rising inflation has grown. This has kicked off an intense search for alternative diversifiers that can help multi-asset portfolios buffer growth or rate shocks. But to add value from a portfolio perspective, an asset should offer an attractive risk/reward or low correlations with other assets, and preferably both. Over the last 35 years, bonds served this role as they delivered attractive risk-adjusted returns while being negatively correlated with equities.

With 20% ($14tn) of global debt offering negative yields, the hurdle rate for other assets to compete with bonds for the role of diversifier has declined. As a result, the lack of cash flow or yield from cryptocurrencies has become less of a concern, especially as the same is true for gold and most DM FX. And bitcoin, which was the first cryptocurrency and has the largest market cap today, has posted strong risk-adjusted returns mostly uncorrelated with traditional assets. But the history of bitcoin has been short and volatile—with a large proportion of that volatility idiosyncratic—making it difficult to assess how much of a beneficial role it could play in multi-asset portfolios. And institutional and other constraints remain headwinds for broader investor adoption.

Small allocation, big impact

Just a small allocation to bitcoin in a standard US 60/40 portfolio would have enhanced risk-adjusted returns materially since 2014 (while bitcoin prices are available from mid-2010, we use prices since 2014 as bitcoin was not easily accessible to investors before then), even as balanced portfolios performed strongly on their own. Driving the enhanced performance was both higher risk-adjusted returns for bitcoin compared to the S&P 500 and US 10y bonds, despite much higher volatility, as well as diversification benefits from relatively low correlations between bitcoin and other assets.

However, bitcoin’s strongest performance contribution to the portfolio resulted from isolated rallies in 2017, 2019 and last year, when it received a major boost from the COVID-19 crisis. Since 2014, bitcoin has actually often declined during equity drawdowns like in 2015, 2018 and 1Q20. These large drawdowns, combined with bitcoin’s high volatility, have eventually outweighed the benefits of having it in a portfolio at higher allocations. Even with just a 5% allocation in a 60/40 portfolio, bitcoin drove roughly 20% of the portfolio’s volatility, while US 10y bonds contributed only 2%. That is likely too much concentrated risk exposure for an institutional multi-asset portfolio, and such high volatility also limits the potential allocations from investors employing risk parity strategies or targeting a specific level of risk in the portfolio.

Strong performance during the rallies in 2017, 2019 and the COVID-19 crisis

One-year rolling return

Source: Bloomberg, Goldman Sachs GIR.

Untested correlations, high idiosyncratic risk

To assess the potential future diversification benefits of having bitcoin in their portfolios, investors need to understand the linkages between bitcoin and macro fundamentals, sentiment and other assets through the cycle. But bitcoin’s history is too short to cover a full business cycle or a period of high inflationary pressures, so it is unclear how bitcoin would behave during a period of large growth and rate shocks. During the COVID-19 crisis, bitcoin became very correlated with other assets and turned out to be a highly levered bet on reflation.

A small allocation to bitcoin has enhanced a 60/40 portfolio in recent years

Since the beginning of 2021, correlations with traditional assets have declined again, although bitcoin remains negatively correlated with the Dollar. While it’s still too early to say for certain, this suggests that investors are treating bitcoin as a hedge against monetary debasement, similar to gold or real assets more broadly.

Low and unstable correlations between bitcoin and other assets, until recently

One-year rolling correlation, weekly changes

Source: Bloomberg, Goldman Sachs GIR.

Despite these correlations, most of the variation in bitcoin has been idiosyncratic. This could be good from a diversification perspective, but only if bitcoin were to have a positive expected return that is both predictable and attractive on a risk-adjusted basis. Given its limited and known supply, the price of bitcoin should primarily depend on investor demand and its perceived value. But investor demand so far seems to be linked to the asset itself rather than macro factors; adoption by retail investors—and recently some institutions—has boosted prices while regulatory and tax concerns—as well as positioning—have driven sharp setbacks. Without more clarity on these idiosyncratic drivers, assessing bitcoin’s future risk/reward remains difficult.

Bitcoin has had high idiosyncratic risk since its inception

One-year rolling R-squared of a regression of bitcoin on S&P 500, US 10y bond, oil, gold, and DXY, weekly changes

Source: Bloomberg, Goldman Sachs GIR.

But, until then, the high and mostly idiosyncratic volatility of bitcoin can make it an unreliable macro hedge, especially over short time horizons, and increases the risk to balanced portfolios from market timing. In contrast to equities and bonds, bitcoin returns have also been more volatile on a monthly vs. daily basis, with both material and sustained drawdowns and rallies. With such volatile assets, more frequent rebalancing to return to target weights can increase drawdowns, as investors need to buy into a drawdown and sell during a rally. But less frequent rebalancing may introduce unintended market timing risks.

More headwinds from institutional constraints

Institutional asset allocators must also consider other factors when assessing potential bitcoin investments. First, the overall size and liquidity of cryptocurrencies is small; the market value of global financial assets (stocks and bonds) is roughly $200tn and the above-ground market value of gold is close to $11tn, while that of bitcoin is only $700bn. And with a multitude of other, smaller cryptocurrencies already in existence and many more that might be launched, picking the winning cryptocurrency is critical. Second, custody and counterparty risks can be difficult and costly to manage. And third, the potential for more regulation of the space, in part due to a lack of transparency and concerns over the carbon footprint of mining, creates significant uncertainty for investors. All of these factors may slow broad adoption from institutional investors.

Crypto’s evolution in terms

**Infrastructure layer**

**Distributed ledger**
A database that is shared and synchronized across multiple sites and geographies by many participants. Each participant can access and own a copy of the ledger, and all changes to the ledger are visible to all participants. Distributed ledgers have no central authority; when a change is made to the ledger, a consensus algorithm is used to verify the change. Information on blockchain-based distributed ledgers is securely stored using cryptography and can be accessed using keys and signatures.

**Blockchain**
A blockchain is a type of distributed ledger that stores a list of records known as blocks. The Bitcoin blockchain was created by Satoshi Nakamoto in 2008 to solve the double-spend problem of decentralized systems—how to verify without a trusted central authority that the same coin was not spent twice—by using a “distributed timestamp server to generate computational proof of the chronological order of transactions.”

**Nodes**
A computer that runs the blockchain software and transmits information across the blockchain network. Nodes are classified according to their roles: mining nodes add transactions to the blockchain through a mining process; full nodes hold and distribute copies of the ledger; super nodes connect full nodes to each other; light nodes are similar to full nodes but hold only a portion of the ledger.

**Mining**
The process of verifying and recording transactions on the blockchain via a consensus algorithm. Miners are rewarded in the form of a block reward. Bitcoin is a mineable cryptocurrency, but not all cryptocurrencies are mineable (see pg. 35 for more detail on bitcoin mining).

**Forks**
When blockchain nodes are not in agreement on a network’s transaction history or rules around what makes a transaction valid, the blockchain may fork. Forks can happen by accident or intentionally. Soft forks are mostly accidental; there is still one blockchain as old nodes can continue to communicate with new nodes. Hard forks are intentional; the blockchain splits into two as old nodes cannot communicate with new nodes.

**Protocol layer**

**Consensus algorithm**
A mechanism by which all the nodes on a blockchain network reach a common agreement about the state of the distributed ledger. Various crypto networks use different consensus algorithms; the two most-recognized are **Proof of Work (PoW)** and **Proof of Stake (PoS)** (see pgs. 26-27 for more detail on which networks use which consensus algorithm).

**Proof of Work (PoW)**
Used by crypto networks like Bitcoin and Litecoin, PoW requires participant nodes to prove that a certain amount of computational effort has been expended. PoW requires a significant amount of computing resources.

**Proof of Stake (PoS)**
Currently used by crypto networks like Cardano and Polkadot, and planned for Ethereum in the future, PoS, unlike PoW, does not involve solving a mathematical puzzle to validate transactions. Instead, participant nodes must stake some amount of cryptocurrency if they want to validate. A random node is then selected as a validator based on how much cryptocurrency is staked, among other factors.
Services layer

Digital asset
An intangible asset created, traded, and stored digitally. Digital assets in the crypto ecosystem include cryptocurrencies and crypto tokens.

Crypto currencies
Native assets of a blockchain network that typically serve as mediums of exchange or stores of value. A cryptocurrency is issued directly by the blockchain protocol on which it runs. They are typically decentralized, built on a blockchain, and secured using cryptography. Cryptocurrencies include bitcoin and ether, the native asset of the Ethereum network, and initial coin offerings.

Crypto tokens
Unlike cryptocurrencies, which are native to a specific network, crypto tokens are created by platforms that build on top of other blockchains. For example, the tokens of Uniswap and Aave—UNI and AAVE—are built on the Ethereum network. Tokens can be used not only as mediums of exchange or stores of value, but also for governance decisions (e.g. voting on changes or upgrades to the protocol) or to access platform services.

The most widely used Ethereum tokens are ERC-20 for fungible tokens and ERC-721 for non-fungible tokens. They each specify how to build functional tokens for their respective uses.

Initial coin offering (ICO)
ICOs are a way for companies to raise capital. During an ICO, a company offers tokens to potential investors in exchange for fiat currency or established cryptocurrencies like bitcoin and ether to fund a project. The tokens are distributed via a blockchain network. One example of an ICO is Filecoin, launched in 2017 as a digital storage platform.

Tokens purchased in an ICO typically do not provide investors shares in the company, but rather grant access to the service or platform.

Smart contracts
Smart contracts are self-executing contracts with the terms of agreement between parties written directly into lines of code. Ethereum is the most popular blockchain for running smart contracts, which are typically written in the programming language Solidity.

Smart contracts are used by decentralized applications to connect to the blockchain.

Applications layer

Decentralized applications (dApps)
Digital applications that exist and run on decentralized blockchains rather than a centralized computer system. Most dApps are currently built on the Ethereum network.

dApps are used by a variety of industries, including finance as decentralized finance apps, gaming, and online gambling.

Decentralized finance (DeFi)
A blockchain-based form of finance that doesn't rely on centralized financial intermediaries like banks, brokerages, or exchanges. Instead, smart contracts are used to offer users traditional financial services like loans, derivatives, and insurance.

Similar to dApps, most DeFi applications are currently built on Ethereum.

Note: Not intended to provide an exhaustive list of terms for each layer.

Mathew McDermott is Global Head of Digital Assets at Goldman Sachs. Below, he discusses institutional interest in crypto assets, and Goldman Sachs’ engagement in the space.

The interviewee is an employee of the Goldman Sachs Global Markets Division (GMD), not Goldman Sachs Research, and the views stated herein reflect those of the interviewee, not Goldman Sachs Research.

### Interview with Mathew McDermott

Allison Nathan: Goldman Sachs has had fits and starts in the crypto space. Why now for a new launch into the space?

Mathew McDermott: Client demand, pure and simple. When we originally explored creating our own digital custody offering and launching a crypto trading desk in 2017/2018, the price action was almost exclusively retail led. What’s different today is the extent of institutional interest, coupled with very strong demand across the wealth management franchise. The product offering is broader as people are looking beyond bitcoin at the potential of the underlying blockchain infrastructure to transform the way markets behave. This has sparked interest in other kinds of cryptocurrencies—ether, dot, etc.—whose value proposition revolves more around what else can be done on blockchains. That, together with a more mature crypto market place with better risk management, execution, and digital custody, have all made it a bit easier for institutions to digest and access the market.

Allison Nathan: What’s the nature of your conversations with institutional clients and their interest in the space?

Mathew McDermott: As a whole, discussions with institutional clients revolve around how they can learn more on the topic and get access to the space—as opposed to questions around what bitcoin or cryptocurrencies are—which was really the main topic just a few years ago. But beyond that, asset managers and macro funds are interested in whether or not crypto fits into their portfolios, and if it does, how to get access to either the physical—by trading the spot instrument on a blockchain—or exposure through other types of products, typically futures. Hedge funds, perhaps unsurprisingly, are more active in this space, and are particularly interested in profiting from the structural liquidity play inherent in the market—earning the basis between going long either the physical or an instrument that provides access on a spot basis to the underlying asset and shorting the future.

Corporate treasurers are interested in two slightly different questions. First, should they be investing in bitcoin on their balance sheets? Especially in places where firms face negative interest rates and fear asset devaluation amid the extraordinary amount of fiscal and monetary stimulus in the economy, having some portion of their balance sheet in bitcoin rather than paying to keep cash on deposit or holding negative yielding government bonds may make sense. And second, should bitcoin be considered a payment mechanism? I think that’s a weaker argument given the inherent inefficiencies in the Bitcoin blockchain in terms of transaction speed. PayPal talks about allowing the use of bitcoin to pay for items, but behind the scenes a company called Paxos is actually converting bitcoin into fiat currency, which is then paid to merchants.

A portion of wealth management clients—high-net-worth individuals and family offices—are already very active in the space and in some sense are leading the way for other investors. They remain interested in bitcoin, but are also increasingly focused on the broader value that cryptocurrencies can bring. They’re looking at ether in the context of the whole decentralized finance (DeFi) ecosystem and how that can really transform financial markets.

Allison Nathan: There seems to be a debate today about whether or not cryptocurrencies can be considered an asset class. Are clients viewing it that way?

Mathew McDermott: Increasingly, yes. Bitcoin is now considered an investable asset. It has its own idiosyncratic risk, partly because it’s still relatively new and going through an adoption phase. And it doesn’t behave as one would intuitively expect relative to other assets given the analogy to digital gold; to date, it’s tended to be more aligned with risk-on assets. But clients and beyond are largely treating it as a new asset class, which is notable—it’s not often that we get to witness the emergence of a new asset class.

Allison Nathan: Are you observing FOMO-related pressure to invest given the extraordinary gains in crypto prices over the past year, and if so, are you concerned that price volatility will diminish client interest?

Mathew McDermott: There’s no doubt that “fear of missing out” (FOMO) is playing a role given how much bitcoin and other crypto assets have appreciated and how many interested parties of all flavors have jumped into this space. If you’re an asset manager or running a macro fund and your closest rivals are all investing and seeing material returns, your investors will naturally wonder why you are not investing. But I see investor interest in crypto enduring; we’ve crossed the Rubicon in terms of institutional buy-in, and there is much greater value in the space than there was three or four years ago.

Allison Nathan: Roughly what percentage of clients that you engage with are interested in the space versus actually active in the space?

Mathew McDermott: That is a good question. Last year we definitely saw many clients exploring rather than executing. From what we see and anecdotally hear that seems to be changing. A survey from our Digital Asset team conducted in early March found that of the 280 clients that responded, 40% have exposure in some form to cryptocurrencies, with 61% expecting their holdings to increase over the next 12 months, and I suspect that would be more now. Another indicator of increased activity is the almost 900% yoy increase in CME bitcoin future daily activity in April.

### Goldman Sachs Global Investment Research

---
Allison Nathan: Goldman Sachs itself is only engaging in the space in a relatively limited way. Why is that?

Mathew McDermott: It's true that we are in early days of our engagement and the regulatory landscape remains in flux, so we're only just starting to offer our clients access to the crypto space. We're currently transacting non-deliverable forwards, which we cash settle, and CME futures on bitcoin and ether, the latter on an agency basis for now. To help facilitate client transactions, we expect to trade the bitcoin CME future and certain pre-agreed upon bitcoin-linked securities on a principal basis in the near future. From a prime brokerage perspective, liquidity has increased dramatically over the past year. Between April 2020 and April 2021, daily bitcoin dollar spot volume increased from ~$300mn to ~$1.5bn, and daily CME bitcoin futures volume grew from ~$200mn to close to ~$2bn. That's a very clear indication of the inflow of institutional demand into this market, which has only just begun. But even though liquidity has increased, it's still difficult for institutions to gain access to the market, which remains quite fragmented. That fragmentation is driving the basis that I mentioned between going long the physical and shorting the future that hedge funds are picking up. And that basis has fluctuated considerably over the last three to six months.

Allison Nathan: How would you rate the liquidity of the products that we trade today?

Mathew McDermott: Liquidity has increased dramatically over the past year. Between April 2020 and April 2021, daily bitcoin dollar spot volume increased from ~$300mn to ~$1.5bn, and daily CME bitcoin futures volume grew from ~$200mn to close to ~$2bn. That's a very clear indication of the inflow of institutional demand into this market, which has only just begun. But even though liquidity has increased, it’s still difficult for institutions to gain access to the market, which remains quite fragmented. That fragmentation is driving the basis that I mentioned between going long the physical and shorting the future that hedge funds are picking up. And that basis has fluctuated considerably over the last three to six months.

Allison Nathan: Beyond ease of access considerations, what are some of the custodial/security challenges institutions face when transacting in the crypto space today, and how have these evolved?

Mathew McDermott: Digital custody is very different from traditional custody in terms of the risks associated with cryptography, public and private keys, etc. But institutions have gotten more comfortable with these risks over the last several years, for two reasons. One, market participants within the crypto space are more institutional-grade today as entities and in terms of their offerings—custodial offerings are a lot more secure and execution and risk management have improved considerably. Many of these entities are now raising capital in the public markets, both to further institutionalize their offerings and credentialize their activities. And two, the quality of custody both in terms of the technology itself as well as the products around it have evolved with the market. Security around cold storage—where the preponderance of institutional assets sits—has fundamentally improved; multi-signature options are available, the private key can be sharded, etc. And insurance offerings associated with hot storage, which is more vulnerable to theft, have also grown, reflecting the greater confidence from an insurers’ perspective. All of that has helped institutions feel more comfortable participating in the crypto market.

Allison Nathan: What are you hearing from clients are their biggest constraints to increased involvement in crypto?

Mathew McDermott: There are three key constraints. The first is mandate limitations. For corporates, increased involvement often depends on whether their board feels such involvement makes sense given the nature of the company and its objectives. And some investment funds and asset managers don’t have the authority to invest a portion of their portfolios in crypto. The second constraint is the ease of access that I mentioned: how easily can clients gain exposure to the market, is the liquidity sufficient to meet their needs, and are they comfortable enough with the custody and security aspects of managing these assets? And the third constraint, perhaps more philosophical, is whether having crypto exposure is the right thing to do and makes sense for their portfolios, balance sheets, etc. But as evidenced by the increased inflows, more and more entities are becoming comfortable with having some exposure to the crypto space.

Allison Nathan: Do you hear concerns from investors about the environmental footprint of proof of work crypto assets like bitcoin, especially given increased investor focus on ESG today?

Mathew McDermott: A number of potential investors have voiced concerns and understandably want to delve more into that aspect of crypto assets and really understand it. Generally, the environmental concerns have not caused investors to fully close the door, but they are looking at improved sustainability options. Investors are intrigued to hear about miners leveraging renewable energy sources to mine crypto assets. And carbon neutral funds are emerging, that, for example, calculate the carbon cost of crypto mining, and buy credits to offset their environmental impact.

Allison Nathan: What risks worry you the most as we and our clients increase engagement in the space?

Mathew McDermott: A key concern is inconsistent regulatory actions around the globe that impede the further development of the crypto space, or the ability of more regulated entities to engage within it. It feels like the regulatory tone has turned more constructive, but I certainly wouldn’t want to be complacent. And the other major concern is fraud, both in terms of storage and nefarious activity on the blockchain. Particularly as it relates to hot storage, we’re only one big fraud away from a very negative impact on the market. But it’s reassuring to watch large crypto companies with significant increases in assets under management actually manage that growth without any noticeable increase in fraudulent activity.

1 A testnet is used by developers to test and troubleshoot all the features of a blockchain network. After a successful testnet, a mainnet version of the blockchain is launched, and all transactions are broadcast, verified, and recorded. The mainnet phase also sees the deployment of a native token rather than the previously issued Ethereum-based token, which is swapped for the new token during a process known as the mainnet swap.

Alan Cohen served as Senior Policy Advisor to former SEC Chairman Jay Clayton from 2017 to 2021, and was the Global Head of Compliance at Goldman Sachs from 2004 to 2017. Below, he discusses the current state of cryptocurrency regulation in the US.

*The views stated herein are those of the interviewee and do not necessarily reflect those of Goldman Sachs.*

**Allison Nathan: How do regulators treat crypto assets today—as securities, commodities, currencies, or something else?**

**Alan Cohen:** No single US regulator oversees all aspects of crypto assets. Different regulators are focused on different applications and functions of blockchain technology. For example, if a custodian of a cryptocurrency is a bank, then the relevant banking regulator—the Office of the Comptroller of the Currency (OCC), the Fed, or the FDIC—will issue rules or guidance on how that custody function should be performed. The OCC did just that in late 2020, authorizing regulated banks to participate in certain blockchain nodes, to custody client cryptocurrency assets and to facilitate cryptocurrency payments. It makes sense that banking regulators would prescribe how regulated banks under their supervision should address this class of assets.

**Allison Nathan: How focused are regulators on cryptocurrencies today, and what areas are they most focused on?**

**Alan Cohen:** The SEC and other US financial regulators are increasingly focused on cryptocurrencies and blockchain technology as the space continues to evolve. Regulatory activity will almost certainly focus on three main areas in which crypto assets have the potential for greatest market penetration and disruption—application of distributed ledger technology (DLT) to facilitate financial transactions, the use of crypto assets and the blockchain to make payments, and investing in crypto assets as a store of value. Many companies have sought to deploy DLT that allows parties to record, track, verify and store transactions of value, e.g., financial and real estate transactions, without the need for a trusted intermediary to verify the transaction, and in a way in which the stored information is impervious to tampering or destruction.

The application of DLT to highly regulated activities in financial transactions is still in its infancy, with both large and small players developing solutions and applications. For example, in the area of securities transactions, firms are undertaking the digitalization or tokenization of shares or other securities of companies, the trading of those digital securities, the clearing and settlement of those transactions, and the recording of those transactions and the ownership of assets—to name just a few applications. Insofar as these innovations will perform highly regulated market functions, the regulators in those areas—such as the SEC in the previous examples—will need to consider whether existing regulations are sufficient to cover these new applications or whether new rules are required. An example of this type of review was the recent SEC guidance on how broker-dealers could custody digital assets, which has enabled greater custody of digital assets by registered broker-dealers.

A second major area of regulatory focus is the application of blockchain technology to fiat currency and the global payments system, which appears to be heading toward a new digital era. On the global stage, the Financial Stability Board (FSB)—comprised of G20 Finance Ministers, central banks, the Bank for International Settlements (BIS) and other international organizations and global standard-setting bodies—is hard at work on an overhaul of the global payments system that will likely embrace crypto assets in the form of fiat digital currency. That new system will replace or supplement the existing SWIFT system that has been the backbone of the global bank-to-bank payments system for decades. These digital currencies are likely to be in the form of sovereign fiat currencies, e.g., a digital dollar, euro or yuan. Of course, China has already begun to implement a digital yuan domestically, which will give its government more control of and transparency into the use of its currency in China. This has set off a global race to adopt fiat currency in digital form. Various European countries have begun to investigate their own digital currencies and the US Treasury and the Fed have announced that they are studying the possibility of a digital dollar.

The implication of fiat digital currencies for existing cryptocurrencies is unclear. But let’s not forget the old adage, “Don’t bet against the Fed.” You might modify that to say: “Don’t bet against the central banks of the world” to relinquish control over their money supply and currency. The evolving regulation of stablecoins—digital assets designed to track an underlying fiat currency or basket of such currencies—provides some insight into the future of cryptocurrency regulation in the US and elsewhere. In an October 2020 FSB Report, the first recommendation tells you all you need to know: “Authorities should have and utilize the necessary powers and tools… to comprehensively regulate, supervise and oversee a [global stablecoin] arrangement and its associated functions and activities, and enforce relevant laws and regulations effectively.” That was followed in December 2020 by a statement released in the US by the President’s Working Group on Financial Markets, which is composed of the leading federal financial regulators, encouraging innovation. But the statement went on to make clear that (1) stablecoins must comply with applicable US legal, regulatory and oversight requirements; and (2) stablecoin participants and arrangements must meet all applicable anti-money laundering (AML) and counter-terrorist financing and sanctions obligations before bringing them to market.

A proposed set of regulations was also issued by FinCEN in December 2020, which the Biden administration will need to finalize. The proposed regulations are designed to ensure that transactions in cryptocurrency are broadly subject to the same AML and related controls as other forms of payment. Those regulations are entirely consistent with the Financial Action Task Force (FATF) standards applied broadly across the globe to prevent AML and terrorist financing. It’s difficult to imagine that cryptocurrencies in whatever form will not be subject to those
same requirements. Financial regulators spent decades doing away with bearer bonds because of the AML, fraud and tax evasion risks posed by the instrument, and it’s unlikely that global regulators will permit cryptocurrencies to take their place in the global financial system. The bottom line is that the anonymity promised by some crypto assets will inevitably meet intense regulatory opposition. The third main area of regulatory focus is cryptocurrencies as a store of value, as an increasing number of institutional and retail investors are focused on investing in cryptocurrencies as an asset class with growth potential. Regulators and investors want markets that are transparent, fair and well regulated. But a very significant percentage of trades—some claim in excess of 90% of all trades—in these assets takes place on markets that are not transparent or regulated in a manner consistent with global market regulatory standards. The notorious instances of clients losing their money when brokers were hacked, custodians disappeared, or market prices were allegedly manipulated partly reflect this lack of regulation. This dearth of regulation will likely remain a key challenge for the cryptocurrency ecosystem.

Allison Nathan: Given these different areas of regulatory focus, which crypto assets is the SEC focused on?

Alan Cohen: The SEC is focused on crypto assets that are, in effect, securities. In the period between 2017 and 2020, the SEC was very active in pursuing securities fraud and other types of cases against Initial Coin Offerings (ICO}s) that were securities masquerading as currencies or commodities. If an offering is a security, then the offering must be done pursuant to the Securities Act of 1933 and trading must occur in a manner permitted under the Securities Exchange Act of 1934, or under exemption to the requirements under those Acts.

Allison Nathan: How does the SEC decide if a crypto asset is a security?

Alan Cohen: The SEC’s Decentralized Autonomous Organization (DAO) Report discusses the elements that the SEC considers in deciding whether a digital offering is a security. As outlined in that report and in subsequent SEC cases, the SEC applies a test set forth in a Supreme Court case, the so-called Howey test, to determine if the offering is a security. Among other factors, Howey test elements include (1) investment of money, (2) in a common enterprise, and (3) with a reasonable expectation of profits derived from the efforts of others. With this in mind, we can distinguish between three types of crypto assets: asset or equity tokens, which represent a claim on an issuer, tokens that are meant as a means of payment or exchange, such as bitcoin, and utility tokens that represent a right to have access to some digital application or service. The first group is considered a security, while the second and third groups generally are not viewed as securities. SEC officials have publicly stated that Bitcoin and Ethereum are sufficiently decentralized networks that neither bitcoin nor ether are securities. And the SEC established the Strategic Hub for Innovation and Financial Technology to foster innovation in DLT, including by providing clear guidance that utility tokens are not securities.

Allison Nathan: What if the SEC finds that an ICO should have been registered as a security and was not?

Alan Cohen: Under US securities laws, a sale of a security confers certain rights to the buyer—including the right to get their money back, a so-called “right of rescission”—in the event that a securities offering should have been registered and was not—as was the case with some ICOs—or if there was fraud in connection with that offering. Two recent cases illustrate that the sale of unregistered securities to investors can have serious consequences for issuers. The SEC successfully sued Telegram, alleging that Grams were unregistered securities. The court agreed, and Telegram had to return the money from the sale of Grams to its investors. In another case, the SEC sued Kik Interactive over its offering of a “Kin” token, which the court preliminarily agreed was a security. There is also a pending case brought by the SEC against Ripple Labs, Inc. and others over its sale of XRP on the same theory. That’s a case worth watching.

Allison Nathan: What will it take for the SEC to approve a cryptocurrency ETF?

Alan Cohen: A number of firms have announced their intention to offer such a product. The SEC’s mission to protect investors, maintain fair, orderly and efficient markets, and to facilitate capital formation will be sharply in focus as regulators assess whether a cryptocurrency ETF should be approved. Indeed, a prerequisite, among other things, for a cryptocurrency ETF will be that regulators and investors are satisfied that underlying market prices are fair, accurate, and transparent. And the recent bout of volatility doesn’t provide much comfort in this regard.

Allison Nathan: If bitcoin and ether are not securities, does that mean that the CFTC regulates trading in them?

Alan Cohen: Not exactly. The mission of the CFTC is “to promote the integrity, resilience, and vibrancy of the US derivatives markets through sound regulation.” That means that the CFTC regulates the derivatives market, but does not directly regulate the underlying market. The CFTC regulates trading in the CME-listed bitcoin and ether futures contracts. In certain instances, it will look through to trading in the underlying market insofar as it impacts the futures market. But it does not regulate that underlying market.

Allison Nathan: Do states regulate the underlying market?

Alan Cohen: New York has been one of the most active states in this space. In 2015, the New York State Department of Financial Services issued regulation for a “BitLicense,” which allows firms to create, issue, transact, and custody virtual currencies. The purpose of the license is to regulate what it calls “Virtual Currency Business Activity”. New York and other states, including Utah, have also amended their banking or trust laws in an effort to foster innovation and capture a share of the future revenue stream associated with this activity.

Allison Nathan: Shouldn’t there be a single federal agency responsible for the regulation of cryptocurrencies?

Alan Cohen: Not necessarily. What is required is close coordination with—and on the federal level and among international standard-setting bodies—the FSB, BIS, International Organization of Securities Commissions (IOSCO) and others. Because of the multitude of applications of blockchain technology across the spectrum of financial transactions—from banking to securities markets to payments to investing—the relevant federal authorities that oversee those markets are best able to assess the benefits and the risks of this technology in those regulated areas.
Allison Nathan: How secure is the blockchain that underlies bitcoin and other cryptocurrencies?

Dan Guido: There are two main facets of blockchain security: the security of the software and the security of how the distributed network is run. Nobody would expect that software written in C++ with its own custom network protocol running on globally distributed machines that provides millions—if not billions—of dollars for a successful hack would be secure, but most of the software running cryptocurrency networks is generally fairly safe. And we know that because, at least for Bitcoin, the software is relatively mature, so a lot of eyes have been prying into it for a long time, and we have actually done source code audits on much of it. But we also know that because there’s a massive reward for not being secure, which no one has reaped. That being said, I would not be surprised if a high severity vulnerability in Bitcoin software was revealed tomorrow. But relative to other blockchain software, it is relatively safe.

Beyond the software itself is the fact that the blockchains that underlie Bitcoin, Ethereum and other crypto networks have no central authority that controls them. Volunteers run nodes—entities that come to a distributed consensus—that accept transactions and attempt to get them incorporated into the blockchain. And then miners compete against each other to construct new blocks on the blockchain. The incentives in that distributed protocol are interesting and sensitive.

People commonly discount the risk of an adversarial network attack on a cryptocurrency blockchain, believing that everyone on a blockchain has an economic incentive to keep it going—that there’s more money in a network that’s running than in a network that’s not. But there have been attacks on blockchains, and it’s possible that certain chain forks attributed to bugs in a consensus protocol were actually deliberately triggered by attackers. We need to remember that some bad actors just want to see the world burn. And current state-level efforts in China and other countries to implement a nationally anointed cryptocurrency make me wonder if public blockchains may become persona non grata in those countries, opening the floodgates for adversarial network attacks by foreign nation-states with the resources to pull them off.

Allison Nathan: What form would such an attack take, and how difficult would it be for a bad actor to execute one?

Dan Guido: An oft-discussed threat is the so-called 51% attack in which a single entity gains control over 51% or more of the mining power in the world, allowing it to invalidate the immutability properties of the blockchain to rewrite history or cause what’s called a double-spend: Suppose Alice tries to give Bob and Eve one bitcoin each, but Alice has only one bitcoin. If those two transactions are submitted to the blockchain at the same time, it’s almost arbitrary which one will be executed first, but the one executed second will fail. Someone with 51% control of the network can make them both succeed. It’s almost impossible to know for certain where miners are located geographically, but there’s evidence that a significant portion of them are concentrated in China, likely due to energy resource availability; several weeks ago, a gas explosion and flood in a coal mine in the Xinjiang region led the Chinese government to shut down all the neighboring cryptocurrency mining farms to conduct fire safety inspections. That was the morning of April 16, and by the end of the day, Bitcoin’s global hash rate had dropped by 50%.

But even with less than 51% of the mining power, bad actors with control over a majority of a blockchain’s nodes can still conduct nefarious activities like denying service to specific users. For example, a nation-state could use their nationwide firewall to block all traffic for a specific Bitcoin address. Importantly, if someone were to manipulate the network in such a way, it could be done so subtly that detecting it would be almost impossible.

Allison Nathan: Have any bad state actors tried to engage in that type of activity?

Dan Guido: To my knowledge, there is no evidence that any state actor has directly targeted the stability of the network, although significant nation-state activity has occurred on cryptocurrencies themselves. Russia has heavily used cryptocurrencies over the last few years. North Korea has mostly focused on attacking endpoints like exchanges and digital wallets. But non-nation-state bad actors have attempted to financially manipulate the network to gain an edge on specific epochs of time to sneak a transaction in and somehow benefit. That’s occurring particularly on the Ethereum network, where many decentralized finance (DeFi) and other activities amenable to exploitation are located.

Allison Nathan: So how can institutional investors getting involved in the space safely engage in it?

Dan Guido: Two important ways: through safe exchanges and safe interactions with an exchange. There’s a mantra in some parts of the blockchain industry, “not my keys, not my bitcoin”, which essentially advocates taking your private keys—and, thus, your bitcoin—showing them under your mattress, and hoping they don’t get stolen. That’s a bad idea. Institutions and people more broadly should be storing their cryptocurrencies on a reputable exchange. But the security of an exchange is not obvious from the outside. Exchanges exist today that have no business being exchanges, operating in unregulated markets or as pure crypto exchanges without any exposure to fiat currency to avoid regulation. Just last month, the CEO of a Turkish cryptocurrency exchange allegedly stole $2 billion from the exchange’s users. And riff-raff in the space just flying by the seat of their pants and getting hacked is prevalent. But the top 10% of centralized exchanges probably have enough resources.
and maturity to have invested in their own security well enough to protect users’ investments. They generally also have ways to architect their internal systems through a segregation of resources, key management, and fund movement processes such that a potential compromise of the exchange wouldn’t be catastrophic. And some of them have built checks into their user interfaces to ensure money isn’t being sent to a null address—which would prevent the funds from ever being accessed again—due to something like a fat-finger mistake.

But the other point of vulnerability is the device used to interact with the exchange. Setting up a high-risk machine like an iPad or Chromebook that is used only to interact with an exchange instead of a general-purpose machine is generally the safest route to take. As long as you’re doing that, the likelihood of your computer being infected with surreptitious malware or ransomware that will steal your cryptocurrency is pretty low. And that’s important because once those funds are gone, they’re unrecoverable.

Allison Nathan: Why are they unrecoverable if all the activity on public blockchains is transparent?

Dan Guido: It’s true that you can see exactly where the cryptocurrency went, but it’s difficult to map that to the point at which a human connects to the blockchain. Funds can also be laundered through different blockchains, and services like tumblers and those that use zero-knowledge proofs can help obfuscate where the cryptocurrency came from. And even if you know exactly who perpetrated the crime, if they’re in a different jurisdiction you may have no legal recourse.

Allison Nathan: How secure are today’s smart contracts?

Dan Guido: We frequently find vulnerabilities in the smart contracts we review. A few months ago we ran Slither—a tool we developed to detect vulnerabilities in smart contracts—on 2,000 new contracts posted to the Ethereum blockchain over a nine-day period. About half of them had known vulnerabilities. Of those, on average, each contract had ten known vulnerable patterns and at least one high severity vulnerability. That’s the consequence of having tools that are really difficult to build secure software with. It’s a wild west out there for developers building applications on the blockchain. Solidity—the language being used—has dozens of different foot guns and opportunities for failure. Developers are generally on their own using stone tools to cobble together houses built of balsa wood and cardboard and trying to scale them up to 20 stories high in a neighborhood that constantly gets lit on fire.

That said, a few firms made early investments in software testing tools that allow them to apply techniques like symbolic execution, abstract interpretation, and security property testing, and have produced highly reliable software capable of managing billions of dollars. But a huge amount of churn exists at the bottom of the market where companies have no access to expertise and no experience of their own, and many end up deploying software that explodes in their faces almost immediately. And even systems that pass formal security evaluations aren’t necessarily secure. Only about half the bugs we find in our security reviews are amenable to being formally proven. Proving the other half requires a human brain, because they’re logical in nature, deal with interactions between the system and the world at large, or just can’t be modeled with a machine. So a tremendous amount of risk remains, even when everything is done right on the code security level.

Allison Nathan: So what worries you most about the underlying technology and infrastructure of the crypto space?

Dan Guido: Smart contracts concern me because the potential for one incident to affect the entire industry is really large. It’s akin to being an insurance provider in a world where every house is built on the beach in Florida. And it’s also important to recognize that very few DeFi systems are truly decentralized; almost all of them have a centralized backdoor or a set of private keys that allow the owner to manipulate account balances or the functionality or state of the system. So the systems are not trustless, even though they’re advertised that way, making it necessary to have trust in the company that deploys the smart contract and the security assessments it utilizes. It’s not enough that an external security firm produced a report; a company may have hired the firm only to do a week-long assessment when the project’s size requires an eight-week assessment. As a result, the security firm will likely have missed something.

And even when secure code is deployed, if the functionality of the underlying blockchain has changed—which, for example, happens every few months on the Ethereum blockchain as it forks—that may inadvertently make existing contracts insecure. So a preponderance of evidence is needed to assess security. That means having an educated team with industry experience, security standards, authentication systems, key management, and regular external security reviews. A single data point isn’t enough; security needs to be thought about holistically.
Interview with Michael Gronager

Michael Gronager is Co-Founder and CEO of Chainalysis, a leading blockchain data, investigations, and compliance company, and was a co-founder of the cryptocurrency exchange Kraken. Below, he discusses the extent to which bitcoin and other cryptocurrencies facilitate illicit activity.

The views stated herein are those of the interviewee and do not necessarily reflect those of Goldman Sachs.

Michael Gronager: Cryptocurrency transactions are commonly perceived to be associated with illicit activity. What does your analysis suggest?

Allison Nathan: Cryptocurrency transactions are commonly perceived to be associated with illicit activity. What does your analysis suggest?

Allison Nathan: Cryptocurrency transactions are commonly perceived to be associated with illicit activity. What does your analysis suggest?

Michael Gronager: Cryptocurrencies are by design permissionless value transfer networks that enable anyone in the world to access and transfer funds. In the early days of cryptocurrencies, this ease of access created a perception that they were an anonymous global money system everyone could use, which attracted interest from criminals. But the interesting thing about blockchain is that every single transaction is public, immutable and never disappears. This visibility has enabled us to create a map of the entire crypto network based on every transaction on the blockchain which, combined with intelligence from the public and private sectors, provides a fairly comprehensive view of the entire crypto ecosystem. By using this map, and looking at different patterns of behavior and the entities involved in transactions, we can track the amount of funds that are being used for various purposes, including legitimate investment and illicit activity. Our analysis shows that in 2020 total illicit activity accounted for around 0.34% of all crypto transactions. That’s down from around 2% of all transactions in 2019, much of which was dominated by a single large Ponzi scheme. Scams are a major use case among criminals that abuse crypto. So a very small share of all crypto transactions today are illicit, which is quite different from the general perception that cryptocurrency activity is dominated by criminals.

Michael Gronager: How certain can you be of the accuracy of these figures?

Allison Nathan: How certain can you be of the accuracy of these figures?

Allison Nathan: How certain can you be of the accuracy of these figures?

Michael Gronager: We are very confident in what we know, as we have a very rigorous, high bar for attributing services to blockchain activity. While it’s true that we don’t necessarily know every entity on the blockchain—especially the smaller ones—the combination of our machine learning and collaboration with customers and partners gives me confidence that we have accurate estimates.

Michael Gronager: How do you identify an illicit transaction?

Allison Nathan: How do you identify an illicit transaction?

Allison Nathan: How do you identify an illicit transaction?

Michael Gronager: The map that we’ve created is basically a map of every entity that transacts on the blockchain, including exchanges such as Binance in Asia and Bitstamp in Europe, blockchain service providers like BlockFi, gaming sites, payment providers, and even Tesla, which accepts bitcoin for vehicle purchases. By identifying certain entities that provide illicit services, it’s possible to track all of the activity that touches those entities via the blockchain. Further, most legitimate entities typically check the identity of their customers. For example, when a customer opens an account with a regulated bitcoin exchange in the US, they have to identify themselves in the same way as when opening a bank account. This usually includes a thorough “know your customer” (KYC) process. What KYC entails is not always standardized, and it could involve everything from requiring a customer to upload their passport to jumping on a video call to confirm their identity. For smaller transactions, KYC rules might only involve confirming a person’s phone number and location via a third party. And even though we can’t see the identities of private wallet owners, if a law enforcement agency sees criminal activity associated with a wallet, they can subpoena the crypto exchange where the individual bought their cryptocurrencies for the personal information associated with the wallet, which allows them to identify the owner and investigate further.

Michael Gronager: But don’t the majority of cryptocurrency transactions take place on exchanges that aren’t regulated and don’t comply with KYC and anti-money laundering (AML) protocols?

Allison Nathan: But don’t the majority of cryptocurrency transactions take place on exchanges that aren’t regulated and don’t comply with KYC and anti-money laundering (AML) protocols?

Allison Nathan: But don’t the majority of cryptocurrency transactions take place on exchanges that aren’t regulated and don’t comply with KYC and anti-money laundering (AML) protocols?

Michael Gronager: The extent of non-compliance has likely been overstated. When I was running Kraken in 2012/13, we logged into all of the major exchanges to see what information they asked users for, and every one required some level of KYC information. Many exchanges that are not formally regulated still comply with standard KYC protocols in practice. Up until last year, for example, there was no regulatory framework for public crypto exchanges in Europe; while some countries had individually rolled out requirements, theoretically many exchanges in the EU could onboard customers without asking for any identification. But most exchanges still collected information on their clients. And there are many other digital breadcrumbs that can enable the identification of a user and facilitate an investigation of criminal activity.

Michael Gronager: So what share of transactions do you think take place on exchanges that don’t comply with KYC?

Allison Nathan: So what share of transactions do you think take place on exchanges that don’t comply with KYC?

Allison Nathan: So what share of transactions do you think take place on exchanges that don’t comply with KYC?

Michael Gronager: I wouldn’t attempt to cite a specific number, but I am confident in saying that a majority of crypto exchanges are collecting some level of identification from users. Some that don’t are peer-to-peer (P2P) exchanges that facilitate people meeting on the street with only a username. In this situation, the transaction is an exchange of cash for crypto, which can be completely anonymous. But many P2P exchanges collect KYC information now too. Another example is some online sites operating out of Eastern Europe where the lack of identification is almost a feature. But people may be afraid to use such sites given the lack of protection. And even in cases where a transaction is associated with an exchange that isn’t KYC complaint, the wallet will likely have transacted with someone that has been identified. So it usually only takes a few steps to identify individuals on the blockchain.
Allison Nathan: What about darknets? Aren’t they difficult to identify?

Michael Gronager: It’s true that darknet markets that facilitate the purchase of weapons, drugs, and other illegal products and services online operate on the “dark web”—parts of the internet that are encrypted or otherwise difficult to access. They also often provide instructions for how users can try to obfuscate their transactions. But despite such efforts, we can generally map out these markets and see their traffic. Once an operation is identified as involving criminal activity, the size and scope of that activity can be tracked because it happens on the blockchain.

Allison Nathan: But isn’t it possible that there are darknet markets out there that you haven’t uncovered?

Michael Gronager: Yes, but the whole idea of a market—whether it’s on the darknet, clearnet, or in person—is to attract customers. To get a customer base, they tend to market their products or services via darknet forums, or some can even be found through a Google search. So, some darknet markets may be really bad at marketing and therefore remain undetected, but that would also probably mean that they don’t have many users and only account for a small share of illicit activity. Even if we can’t identify a darknet market, we can oftentimes identify an entity that looks like a criminal service simply because of its patterns and activities.

Allison Nathan: What patterns do you look at to identify illicit activity?

Michael Gronager: Entities or wallets engaged in illicit activity will try to obfuscate their transactions by enlisting services such as mixers or coinswaps, where someone can swap bitcoin for privacy coins that better preserve their anonymity. An entity interacting with a service like this would be flagged. And as in the case of darknet markets, the mixers on the blockchain are public in the sense that they need a website in order to acquire a customer base, making them easy to identify. The harder part is identifying the users sending funds to these services. But they don’t provide 100% obfuscation from blockchain analysis.

Allison Nathan: Is illicit activity involving fiat-to-crypto exchanges, such as money laundering, captured in what you track?

Michael Gronager: To some extent. Activities like money laundering typically start with criminal funds, which can be identified. A transaction that wouldn’t be captured is a drug lord that buys $10 million of bitcoin on the street and then places it on a P2P exchange. We would not have identified that because it’s basically the job of traditional investigations to flag that the money had a criminal tie before it ended up on the exchange. These transactions aren’t well captured because we have no way of knowing from the onset that they’re criminal.

Allison Nathan: But doesn’t that mean that your methodology likely misses a lot of illicit activity?

Michael Gronager: That’s true in principle. But it’s hard to say why someone looking to hide this type of illicit activity would move into crypto. If you already have cash, crypto is not the best instrument for money laundering. It would make more sense, for example, to build a house and pay the workers in cash and then sell the house than to send funds via crypto where they leave a trace. So it could be done, but I doubt it accounts for a large amount of activity. Crypto transactions only really make sense in facilitating illicit activity that happens online, where using cash isn’t possible, such as buying drugs or a weapon that are mailed to you. As soon as you transact in person, cash is a better anonymity-preserving instrument than crypto, because it leaves no trace. For anything that happens physically, cash is king.

Allison Nathan: What about financial crimes such as tax evasion? Is that captured in your numbers?

Michael Gronager: Someone recently asked me whether the recent rise of crypto prices has been driven by a rise in tax evasion. But that seems unlikely because taxes are typically filed around the end of the year, so that wouldn’t account for the rise in prices since the start of the year. There probably is quite a lot of evasion in the sense of people not paying taxes owed on crypto gains, though. Guidance on these tax liabilities remains unclear, but those taxes will likely have to be paid at some point. But the main point is that blockchain and crypto aren’t simply online enablers of all bad activity and dark money. What they help with is the ability to move money earned through illegal activity abroad more easily and possibly evade recourse so long as they’re in a jurisdiction that’s unlikely to punish them. But that arguably happens already with wire transfers and a lot of other schemes where financial proceeds end up in another jurisdiction where there’s no reach in terms of the law and no willingness to investigate. Crypto gains made in some foreign jurisdictions are also relatively untouchable.

Allison Nathan: Have illicit actors using cryptocurrencies gotten smarter, and how do you keep up?

Michael Gronager: Criminal actors are always looking for areas that offer the least friction and the best opportunities for obfuscation. In the early days of cryptocurrencies, criminal activity was predominately tied to smaller transactions involving relatively normal people buying drugs online. But there’s now a greater concentration of illicit activity tied to larger transactions. As the size of transactions has increased, so too has the desire of criminals to feel safe in their transactions, which has led to greater guidance online about how to try and avoid being tracked.

But the danger of using the blockchain for anything criminal is that transaction records are stored forever. While an obfuscation scheme may work well today, it’s always possible that technology will eventually make it trivial to investigate. And that’s what we’ve seen consistently over time; anything that seemed like a really good obfuscation scheme yesterday has often vanished completely after a year or two and become simple to investigate as we study the activity and figure out how it works. At some point, we understand it well enough to be able to assist the public sector in keeping citizens safe.
Bitcoin: beyond the basics

Step 1: Joining the Network and Buying Bitcoin

- Bitcoin is a peer-to-peer electronic payment system that transfers value between digital wallets. Wallets don’t store currency, but rather interact with the blockchain by generating the necessary information to receive and send money via blockchain transactions.

- Wallets are a combination of a public key and a private key, and based on these keys, an alphanumeric identifier called a public address is generated. Similar to an email address, the public address specifies the location to which coins can be sent to the blockchain, and is shared among users. The private key is used to access funds, and like a password, should not be shared with anyone.

- Security issues present important risks for bitcoin users. Security practices include keeping all private keys offline and keeping a record of where the bitcoin comes from and where it is sent, a practice when moving wallets in and out of cold storage.

- The most popular way to obtain Bitcoin is through an exchange. Currently, the most commonly used type of exchange is not decentralized, and users need to provide personal identification documents per Know Your Customer (KYC) and Anti-Money Laundering (AML) regulations. Bitcoin ATMs and P2P exchanges are alternative ways of obtaining bitcoin.

- How do public and private keys actually look like?

  - Public key: Account number, similar to an e-mail address.
  - Address: Shortened version of the public key, unique to each transaction.
  - Private key: Password granting access to a wallet’s funds

  ```
  0450863a06487aee82f8301a81a4d03b853f3e4b86d8511
  Da08A04887ca5b23f22ob074024353ae299fae9672377716103A
  bc11Adf38855a06F2e187EBc581bA6
  
  1FgKhGsnj3DoZw37Mn2KvVGBQdVSwo
  
  Kx3uWoc1bQRj3dClHycnqsmFLApV6wK7xJuf7cPl1Ygj1h6Y7PQe
  ```

- What does a typical wallet look like?

  - Wallets contain digital records of past transactions, which are used to calculate a total balance.

  ```
  Example: Web/Mobile Wallet
  
  Send BTC
  Request BTC
  
  Transaction History
  
  Received Bitcoin (4/23/2021)  0.002BTC (+$100)
  Sent Bitcoin (4/23/2021)     -0.004BTC (-$200)
  Purchased Bitcoin (4/23/2021) 0.008BTC (+$400)
  ```

Step 2: Transacting in Bitcoin

- Bitcoin can be transferred between wallets in exchange for other currencies or goods/services. There are three key variables in a bitcoin transaction: an amount, an input—the address from which the bitcoins are sent—and an output—the address that receives the funds. To make a transaction, users need to enter their private key, the amount of bitcoins they want to send, and the output address. A digital signature is then generated from the private key, and the transaction is announced to the network.

- The transaction is included in a block, which is attached to the previous block to be added to the network’s public ledger, the blockchain. The blockchain does not track account balances. Rather, it keeps a record of where the bitcoin comes from and which address it is sent to. Therefore, the transaction input must match a past transaction, not the value being transferred.

- If a user makes a transaction worth less than the total amount of bitcoin they have, change is returned to the user. For example, assume User A has a total balance of 10BTC, received through two previous transactions of 6BTC and 4BTC. User A wants to send 2BTC to User B. To do so, User A sends 4BTC to User B and sends the change back to himself. This change is less any transaction fees that User A incurs, which are based on the size of the transaction (bytes). And the change does not go back to the original output—it will go to a new address under the user’s control.

- The transaction is not immediately processed. Instead, it enters a pool of pending transactions and goes through the verification process (see Step 3: Verifying Bitcoin Transactions).

- How are bitcoin transactions recorded?

  ```
  Example: User A Sends 2BTC to User B
  
  Sender | Address | Input (BTC) |
  User A | 14O7x8pWz | 4.0 |
  
  Receiver | Address | Output (BTC) |
  User B | 12rgbuMEv | 2.0 |
  User A | 1EmDxbnu | 2.0-fees |
  
  Every transaction in the blockchain is tied to a unique identifier known as a transaction hash, which is a 64-character random string of letters and numbers. Transactions can be tracked using this identifier.

  Example ID: 081Bd8aZ2f6c9A00770cd4571c246d9c3c4bd49 0bec66960df684fae618c68
  ```

Goldman Sachs Global Investment Research
Step 3: Verifying Bitcoin Transactions

• In order for transactions to be recorded on the blockchain, they must be verified by miners. Miners can be individuals or pools of people. Most mining today is conducted by pools of miners.

• First, miners identify whether a transaction is valid. Bitcoin senders must have both the proper authority to send funds and the necessary funds to back the transaction. Once the transaction is validated, it is packaged into a block with other valid transactions. Blocks have a maximum size of 1MB.

• Miners then compete against each other to be the first to add their block to the blockchain by solving a complex mathematical puzzle and including the answer in the block. The puzzle is to find a number that, when combined with the data in the block and passed through a hash function—which converts input data of any size into output data of a fixed length—produces a result within a certain range. The result is called a nonce, which is an integer between 0 and 4,294,967,296.

• Miners find the nonce effectively by guessing what it is. The more computing power a miner has, the more guessing calculations he can perform. The hash function is applied to the combination of a guessed number and the data in the block, and the resulting hash will begin with a certain number of zeros—which determines the difficulty of the calculation. This difficulty is frequently adjusted to ensure that it takes an average of 10 minutes to process a block.

• The first miner to get a resulting hash within the proper range alerts the network, and all other miners stop working on the block at that point. As a reward, the winning miner gets compensated with some new bitcoin. The amount of the reward decreases over time, halving around every four years.

• Importantly, the hashing process puts a timestamp on all transactions contained within each block. It also links the data from new transactions to information from past blocks. Therefore, transactions can’t be undone or tampered with, because that would require redoing all the blocks that came after the original block.

Step 4: Creating New Bitcoins

• In addition to receiving rewards for verifying transactions and maintaining the blockchain, miners also receive transaction fees. These are payments by bitcoin users to ensure that their transactions go through quickly given the limited throughput of the bitcoin network (approx. 4.6 transactions per second). Therefore, increases in transaction volume have led to an increase in transaction fees paid to miners.

• Bitcoin’s founder set a limit for the maximum supply of bitcoin that will ever be in circulation at 21 mm. Today, there are approx. 18.7 mm in circulation, although some coins have likely been lost. Given the current halving rate, the final bitcoin is expected to be mined in 2140.

• While it’s technically feasible to change the 21 mm limit if the community chooses to do so, the bitcoin community has long stood in favor of the limit.

• Once the 21 mm limit is reached, transaction costs may need to significantly increase to incentivize miners to continue maintaining the blockchain, since there will not be any more rewards received from mining a new block.
Watching

- Globally, we expect above-consensus growth of 6.6% in 2021. Our optimism reflects the view that post-vaccination reopening, accommodative monetary and fiscal policy, pent-up savings, and limited scarring effects will support a continued recovery in economic activity, though the spread of more infectious virus strains poses risks.

- In the US, we expect above-consensus full-year growth of 7.0% in 2021 on the back of significant fiscal stimulus and widespread immunization—with 50% of the population expected to be vaccinated by mid-June. We expect the unemployment rate to fall to 4% by year end, and see core PCE inflation peaking at 2.8% in May before ending the year at 2.2%.

- The Fed has adopted outcome-based forward guidance for asset purchases, and we expect tapering to begin in 1Q22. Under our assumptions that tapering at a $15bn per meeting pace will take up all of 2022 and that the FOMC will then want to take a break before considering rate hikes, liftoff would not be on the table for another two years. On the fiscal policy front, we expect the passage of additional spending focused on infrastructure, social benefits, and long-term investment totaling around $3.3tn over 10 years in Q3, which we expect will be partially offset via higher taxes.

- In the Euro area, we expect above-consensus full-year growth of 5.0% in 2021 on the back of widespread immunization—with 50% of the population of the EMU-4 countries expected to be vaccinated by mid-June. We look for gradual increase in underlying core inflation to 1.5% in Q21.

- We expect the ECB will maintain a pace of PEPP purchases of around EUR 20bn per week through Q2 and exhaust the full PEPP envelope by mid-2022, but believe it will keep rates on hold until 2025. We expect the strategy review to conclude in September with a symmetric 2% aim and enhanced forward guidance to signal that the Governing Council intends to keep policy highly expansionary well into the recovery.

- In China, we think the economic recovery from the COVID-19 shock is essentially complete, and we expect 2021 real GDP growth of 8.5%. We view the risks to this forecast as broadly balanced, with the potential for stronger-than-expected exports posing upside risk and the recent tightening of financial conditions and emission-related industrial output curbs posing downside risks.

- WATCH CORONAVIRUS. While the trajectory of the coronavirus remains highly uncertain, our base case assumes that rising immunity owing to a combination of vaccination and prior infection will drive a continued recovery in global economic activity this year. We expect a majority of people in all of the major economies to have some immunity to COVID-19 by end-2021.

Forecasts

Source: Bloomberg, Goldman Sachs Global Investment Research. For important disclosures, see the Disclosure Appendix or go to www.gs.com/research/hedge.html.

Market pricing as of May 20, 2021.
**Current Activity Indicator (CAI)**

GS CAIs measure the growth signal in a broad range of weekly and monthly indicators, offering an alternative to Gross Domestic Product (GDP). GDP is an imperfect guide to current activity: In most countries, it is only available quarterly and is released with a substantial delay, and its initial estimates are often heavily revised. GDP also ignores important measures of real activity, such as employment and the purchasing managers’ indexes (PMIs). All of these problems reduce the effectiveness of GDP for investment and policy decisions. Our CAIs aim to address GDP’s shortcomings and provide a timelier read on the pace of growth.

**Dynamic Equilibrium Exchange Rates (DEER)**

The GSDEER framework establishes an equilibrium (or “fair”) value of the real exchange rate based on relative productivity and terms-of-trade differentials.

**Financial Conditions Index (FCI)**

GS FCIs gauge the “looseness” or “tightness” of financial conditions across the world’s major economies, incorporating variables that directly affect spending on domestically produced goods and services. FCIs can provide valuable information about the economic growth outlook and the direct and indirect effects of monetary policy on real economic activity.

FCIs for the G10 economies are calculated as a weighted average of a policy rate, a long-term risk-free bond yield, a corporate credit spread, an equity price variable, and a trade-weighted exchange rate; the Euro area FCI also includes a sovereign credit spread. The weights mirror the effects of the financial variables on real GDP growth in our models over a one-year horizon. FCIs for emerging markets are calculated as a weighted average of a short-term interest rate, a long-term swap rate, a CDS spread, an equity price variable, a trade-weighted exchange rate, and—in economies with large foreign-currency-denominated debt stocks—a debt-weighted exchange rate index.

**Goldman Sachs Analyst Index (GSAI)**

The US GSAI is based on a monthly survey of GS equity analysts to obtain their assessments of business conditions in the industries they follow. The results provide timely “bottom-up” information about US economic activity to supplement and cross-check our analysis of “top-down” data. Based on analysts’ responses, we create a diffusion index for economic activity comparable to the ISM’s indexes for activity in the manufacturing and nonmanufacturing sectors.

**Macro-Data Assessment Platform (MAP)**

GS MAP scores facilitate rapid interpretation of new data releases for economic indicators worldwide. MAP summarizes the importance of a specific data release (i.e., its historical correlation with GDP) and the degree of surprise relative to the consensus forecast. The sign on the degree of surprise characterizes underperformance with a negative number and outperformance with a positive number. Each of these two components is ranked on a scale from 0 to 5, with the MAP score being the product of the two, i.e., from -25 to +25. For example, a MAP score of +20 (5;+4) would indicate that the data has a very high correlation to GDP (5) and that it came out well above consensus expectations (+4), for a total MAP value of +20.

Disclosure Appendix

Reg AC
We, Allison Nathan, Jenny Grimberg, Gabe Lipton Galbraith, Jeffrey Currie, Christian Mueller-Glissmann, Zach Pandi, and Mikhail Sprogis hereby certify that all of the views expressed in this report accurately reflect our personal views, which have not been influenced by considerations of the firm’s businesses or client relationships.

Unless otherwise stated, the individuals listed on the cover page of this report are analysts in Goldman Sachs’ Global Investment Research division.

Regulatory disclosures
Disclosures required by United States laws and regulations
See company-specific regulatory disclosures above for any of the following disclosures required as to companies referred to in this report: manager or co-manager in a pending transaction; 1% or other ownership; compensation for certain services; types of client relationships; managed/co-managed public offerings in prior periods; directorships; for equity securities, market making and/or specialist role. Goldman Sachs trades or may trade as a principal in debt securities (or in related derivatives) of issuers discussed in this report.

The following are additional required disclosures: Ownership and material conflicts of interest: Goldman Sachs policy prohibits its analysts, professionals reporting to analysts and members of their households from owning securities of any company in the analyst’s area of coverage. Analyst compensation: Analysts are paid in part based on the profitability of Goldman Sachs, which includes investment banking revenues. Analyst as officer or director: Goldman Sachs policy generally prohibits its analysts, persons reporting to analysts or members of their households from serving as an officer, director or advisor of any company in the analyst’s area of coverage. Non-U.S. Analysts: Non-U.S. analysts may not have certain personal relationships with Goldman Sachs (Subs). Co-tapered country reports subject to FINRA Rule 2241 or FINRA Rule 2242 restrictions on communications with subject company, public appearances and trading securities held by the analysts.

Additional disclosures required under the laws and regulations of jurisdictions other than the United States
The following disclosures are those required by the jurisdiction indicated, except to the extent already made above pursuant to United States laws and regulations. Australia: Goldman Sachs Australia Pty Ltd and its affiliates are not authorised deposit-taking institutions (as that term is defined in the Banking Act 1959 (Cth)) in Australia and do not provide banking services, nor carry on a banking business, in Australia. This research, and any access to it, is intended only for "wholesale clients" within the meaning of the Australian Corporations Act, unless otherwise agreed by Goldman Sachs. In producing research reports, members of the Global Investment Research Division of Goldman Sachs Australia may attend site visits and other meetings hosted by the companies and other entities which are the subject of its research reports. In some instances the costs of such site visits or meetings may be met in part or in whole by the issuers concerned if Goldman Sachs Australia considers it is appropriate and reasonable in the specific circumstances relating to the site visit or meeting. To the extent that the contents of this document contains any financial product advice, it is general advice only and has been prepared by Goldman Sachs Australia without taking into account a client’s objectives, financial situation or needs. A client should, before acting on any such advice, consider the appropriateness of the advice having regard to the client’s own objectives, financial situation and needs. A copy of certain Goldman Sachs Australia and New Zealand disclosure of interests and a copy of Goldman Sachs’ Australian Sell-Side Research Independence Policy Statement are available at: https://www.goldmansachs.com/disclosures/australia-new-zealand/index.html. Brazil: Disclosure information in relation to CVM Resolution n. 20 is available at https://www.gs.com/worldwide/brasil/area/gir/index.html. Where applicable, the Brazil-registered analyst primarily responsible for the content of this research report, as defined in Article 20 of CVM Resolution n. 20, is the first author named at the beginning of this report, unless indicated otherwise at the end of the text. Canada: Goldman Sachs Canada Inc. is an affiliate of The Goldman Sachs Group Inc. and therefore included in the company specific disclosures relating to Goldman Sachs (as defined above). Goldman Sachs Canada Inc. has approved of, and agreed to take responsibility for, this research report in Canada if and to the extent that Goldman Sachs Canada Inc. disseminates this research report to its clients. Hong Kong: Further information on the securities of covered companies referred to in this research may be obtained on request from Goldman Sachs (Asia) L.L.C. India: Further information on the subject company or companies referred to in this research may be obtained from Goldman Sachs (India) Securities Private Limited, Research Analyst - SEBI Registration Number INH000001493, 961-A, Rational House, Appasaheb Marathe Marg, Prabhadevi, Mumbai 400 025, India, Corporate Identity Number U74140MH2006FTC160634, Phone +91 22 6616 9000, Fax +91 22 6616 9001. Goldman Sachs may beneficially own 1% or more of the securities (as such term is defined in clause 2 (h) the Indian Securities Contracts (Regulation) Act, 1956) of the subject company or companies referred to in this research report. Japan: See below. Korea: This research, and any access to it, is intended only for "professional investors" within the meaning of the Financial Services and Capital Markets Act, unless otherwise agreed by Goldman Sachs. Further information on the subject company or companies referred to in this research may be obtained from Goldman Sachs (Asia) L.L.C., Seoul Branch. New Zealand: Goldman Sachs New Zealand Limited and its affiliates are neither "registered banks" nor "deposit takers" (as defined in the Reserve Bank of New Zealand Act 1989) in New Zealand. This research, and any access to it, is intended for "wholesale clients" (as defined in the Financial Advisers Act 2008) unless otherwise agreed by Goldman Sachs. A copy of certain Goldman Sachs Australia and New Zealand disclosure of interests is available at: https://www.goldmansachs.com/disclosures/australia-new-zealand/index.html. Russia: Research reports distributed in the Russian Federation are not advertising as defined in the Russian legislation, but are information and analysis not having product promotion as their main purpose and do not provide appraisal within the meaning of the Russian legislation on appraisal activity. Research reports do not constitute a personalized investment recommendation as defined in Russian laws and regulations, are not addressed to a specific client, and are prepared without analyzing the financial circumstances, investment profiles or risk profiles of clients. Goldman Sachs assumes no responsibility for any investment decisions that may be taken by a client or any other person based on this research report. Singapore: Goldman Sachs (Singapore) Pte. (Company Number: 198602165W), which is regulated by the Monetary Authority of Singapore, accepts legal responsibility for this research, and should be contacted with respect to any matters arising from, or in connection with, this research. Taiwan: This material is for reference only and must not be reprinted without permission. Investors should carefully consider their own investment risk. Investment results are the responsibility of the individual investor. United Kingdom: Persons who would be categorized as retail clients in the United Kingdom, as such term is defined in the rules of the Financial Conduct Authority, should read this research in conjunction with prior Goldman Sachs research on the covered companies referred to herein and should refer to the risk warnings that have been sent to them by Goldman Sachs International. A copy of these risk warnings, and a glossary of certain financial terms used in this report, are available from Goldman Sachs International on request. European Union and United Kingdom: Disclosure information in relation to Article 6 (2) of the European Commission Delegated Regulation (EU) (2016/958) supplementing Regulation (EU) No 596/2014 of the European Parliament and of the Council (including as that Delegated Regulation is implemented into United Kingdom domestic law and regulation following the United Kingdom’s departure from the European Union and the European Economic Area) with regard to regulatory technical standards for the technical arrangements for objective presentation of investment recommendations or other information recommending or suggesting an investment strategy and for disclosure of particular interests or indications of conflicts of interest is available at https://www.gs.com/disclosures/europenepolicy.html which states the European Policy for Managing Conflicts of Interest in Connection with Investment Research.
Japan: Goldman Sachs Japan Co., Ltd. is a Financial Instrument Dealer registered with the Kanto Financial Bureau under registration number Kinsho 69, and a member of Japan Securities Dealers Association, Financial Futures Association of Japan and Type II Financial Instruments Firms Association. Sales and purchase of equities are subject to commission pre-determined with clients plus consumption tax. See company-specific disclosures as to any applicable disclosures required by the Japanese stock exchanges, the Japanese Securities Dealers Association or the Japanese Securities Finance Company.

Global product; distributing entities

The Global Investment Research Division of Goldman Sachs produces and distributes research products for clients of Goldman Sachs on a global basis. Analysts based in Goldman Sachs offices around the world produce research on industries and companies, and research on macroeconomics, currencies, commodities and portfolio strategy. This research is disseminated in Australia by Goldman Sachs Australia Pty Ltd (ABN 21 006 797 897); in Brazil by Goldman Sachs do Brasil Corretora de Títulos e Valores Mobiliários S.A.; Public Communication Channel Goldman Sachs Brazil: 0800 727 5764 and / or contato@goldmanbrasil@gs.com. Available Weekdays (except holidays), from 9am to 6pm. Canal de Comunicação com o Público Goldman Sachs Brasil: 0800 727 5764 e/ou contato@goldmanbrasil@gs.com. Horário de funcionamento: segunda-feira à sexta-feira (exceto feriados), das 9h às 18h; in Canada by either Goldman Sachs Canada Inc. or Goldman Sachs & Co. LLC; in Hong Kong by Goldman Sachs (Asia) L.L.C.; in India by Goldman Sachs (India) Securities Private Ltd.; in Japan by Goldman Sachs Japan Co., Ltd.; in the Republic of Korea by Goldman Sachs (Asia) L.L.C., Seoul Branch; in New Zealand by Goldman Sachs New Zealand Limited; in Russia by OOO Goldman Sachs; in Singapore by Goldman Sachs (Singapore) Pte. (Company Number: 198802165W); and in the United States of America by Goldman Sachs & Co. LLC. Goldman Sachs International has approved this research in connection with its distribution in the United Kingdom.

Effective from the date of the United Kingdom’s departure from the European Union and the European Economic Area (“Brexit Day”) the following information with respect to distributing entities will apply: Goldman Sachs International ("GSI"), authorised by the Prudential Regulation Authority ("PRA") and regulated by the Financial Conduct Authority ("FCA") and the PRA, has approved this research in connection with its distribution in the United Kingdom.

General disclosures

This research is for our clients only. Other than disclosures relating to Goldman Sachs, this research is based on current public information that we consider reliable, but we do not represent it as accurate or complete, and it should not be relied on as such. The information, opinions, estimates and forecasts contained herein are as of the date hereof and are subject to change without prior notification. We seek to update our research as appropriate, but various regulations may prevent us from doing so. Other than certain industry reports published on a periodic basis, the large majority of reports are published at irregular intervals as appropriate in the analyst’s judgment.

Goldman Sachs conducts a global full-service, integrated investment banking, investment management, and brokerage business. We have investment banking and other business relationships with a substantial percentage of the companies covered by our Global Investment Research Division. Goldman Sachs & Co. LLC, the United States broker dealer, is a member of SIPC (https://www.sipc.org).

Our salespeople, traders, and other professionals may provide oral or written market commentary or trading strategies to our clients and principal trading desks that reflect opinions that are contrary to the opinions expressed in this research. Our asset management area, principal trading desks and our other professionals, including traders and other professionals or members of their household, may have positions in the products mentioned that are inconsistent with the recommendations or views expressed in this research.

We and our affiliates, officers, directors, and employees, will from time to time have long or short positions in, act as principal in, and buy or sell, the securities or derivatives, if any, referred to in this research, unless otherwise provided by regulation or Goldman Sachs policy.

The views attributed to third party presenters at Goldman Sachs arranged conferences, including individuals from other parts of Goldman Sachs, do not necessarily reflect those of Goldman Investment Research and are not an official view of Goldman Sachs.

This research is focused on investment themes across markets, industries and sectors. It does not attempt to distinguish between the prospects or performance of, or provide analysis of, individual companies within any industry or sector we describe.

Any trading recommendation in this research relating to an equity or credit security or securities within an industry or sector is reflective of the investment theme being discussed and is not a recommendation of any such security in isolation.

This research is not an offer to sell or the solicitation of an offer to buy any security in any jurisdiction where such an offer or solicitation would be illegal. It does not constitute a personal recommendation or take into account the particular investment objectives, financial situations, or needs of individual clients. Clients should consider whether any advice or recommendation in this research is suitable for their particular circumstances and, if appropriate, seek professional advice, including tax advice. The price and value of investments referred to in this research and the income from them may fluctuate. Past performance is not a guide to future performance, future returns are not guaranteed, and a loss of original capital may occur. Fluctuations in exchange rates could have adverse effects on the value or price of, or income derived from, certain investments.

Certain transactions, including those involving futures, options, and other derivatives, give rise to substantial risk and are not suitable for all investors. Investors should review current options and futures disclosure documents which are available from Goldman Sachs sales representatives at https://www.theccc.org/about/publications/character-risks.jsp and https://www.fiadocumentation.org/fia/regulatory-disclosures_1/fia-uniform-
futures-and-options-on-futures-risk-disclosures-booklet-pdf-version-2018. Transaction costs may be significant in option strategies calling for multiple purchase and sales of options such as spreads. Supporting documentation will be supplied upon request.

**Differing Levels of Service provided by Global Investment Research:** The level and types of services provided to you by the Global Investment Research division of GS may vary as compared to that provided to internal and other external clients of GS, depending on various factors including your individual preferences as to the frequency and manner of receiving communication, your risk profile and investment focus and perspective (e.g., marketwide, sector specific, long term, short term), the size and scope of your overall client relationship with GS, and legal and regulatory constraints. As an example, certain clients may request to receive notifications when research on specific securities is published, and certain clients may request that specific data underlying analysts’ fundamental analysis available on our internal client websites be delivered to them electronically through data feeds or otherwise. No change to an analyst’s fundamental research views (e.g., ratings, price targets, or material changes to earnings estimates for equity securities), will be communicated to any client prior to inclusion of such information in a research report broadly disseminated through electronic publication to our internal client websites or through other means, as necessary, to all clients who are entitled to receive such reports. All research reports are disseminated and available to all clients simultaneously through electronic publication to our internal client websites. Not all research content is redistributed to our clients or available to third-party aggregators, nor is Goldman Sachs responsible for the redistribution of our research by third party aggregators. For research, models or other data related to one or more securities, markets or asset classes (including related services) that may be available to you, please contact your GS representative or go to [https://research.gs.com](https://research.gs.com).

Disclosure information is also available at [https://www.gs.com/research/hedge.html](https://www.gs.com/research/hedge.html) or from Research Compliance, 200 West Street, New York, NY 10282.
